TOTAL POSITIVITY, SCHUBERT POSITIVITY, AND
GEOMETRIC SATAKE

THOMAS LAM AND KONSTANZE RIETSCH

ABSTRACT. Let $G$ be a simple, simply-connected complex algebraic group, and let $X \subseteq G^\vee$ be the centraliser of a principal nilpotent. Ginzburg and Peterson independently related the ring of functions on $X$ with the homology ring of the affine Grassmannian $Gr_G$. Peterson furthermore connected $X$ to the quantum cohomology rings of partial flag varieties $G/P$. In this paper we study three notions of positivity for $X$: (1) Schubert positivity arising via Peterson’s work, (2) Lusztig’s total positivity and (3) Mirković-Vilonen positivity obtained from the MV-cycles in $Gr_G$. The first main theorem establishes that these three notions of positivity coincide. Our second main theorem proves a parametrisation of the totally nonnegative part of $X$, confirming a conjecture of the second author.

In type A the parametrisation and relationship with Schubert positivity were proved earlier by the second author. Here we tackle the general type case and also introduce a crucial new connection with the affine Grassmannian and geometric Satake correspondence.

1. INTRODUCTION

Let $G$ be a simply connected, semisimple complex linear algebraic group, split over $\mathbb{R}$, and let $G^\vee$ be its Langlands dual group (over $\mathbb{C}$). The Peterson variety $Y$ may be viewed as the compactification of the stabilizer $X := G_\vee^F$ of a standard principal nilpotent $F$ in $(g^\vee)^*$ (with respect to the coadjoint representation of $G^\vee$), which one obtains by embedding $X$ into the Langlands dual flag variety $G^\vee/B^\vee$ and taking the closure there.

Ginzburg [13] and Peterson [32] independently showed that the coordinate ring $O(X)$ of the variety $X$ was isomorphic to the homology $H_*(Gr_G)$ of the affine Grassmannian $Gr_G$ of $G$, and Peterson discovered moreover that the compactification $Y$ encodes the quantum cohomology rings of all of the flag varieties $G/P$. Peterson’s remarkable work in particular exhibited explicit homomorphisms between localizations of $qH^*(G/P, \mathbb{C})$ and $H_*(Gr_G, \mathbb{C})$ taking quantum Schubert classes $\sigma_w^\mu$ to affine homology Schubert classes $\xi_x$. These homomorphisms were verified in [25].

The first aim of this paper is to compare different notions of positivity for the real points of $X$: (i) the affine Schubert positive part $X_{>0}^a$ where affine Schubert classes $\xi_x$ take positive values via Ginzburg and Peterson’s isomorphism $H_*(Gr_G) \simeq O(X)$; (ii) the totally positive part $X_{>0} := X \cap U_{>0}$ in the sense of Lusztig [27]; and (iii) the Mirković-Vilonen positive part $X_{>0}^{MV}$ where the classes of the Mirković-Vilonen cycles from the geometric Satake correspondence [30] take positive values.

Key words and phrases. Flag varieties, quantum cohomology, total positivity.

TL was supported by NSF grants DMS-0901111 and DMS-1160726, and by a Sloan Fellowship.
KR was funded by EPSRC grant EP/D071305/1.
Our first main theorem (Theorem 7.1) states that these three notions of positivity coincide. For $G$ of type $A$ the coincidence $X_{a>0}^\mathfrak{A} = X_{>0}$ was already established in [36], where instead of $X_{a>0}^\mathfrak{A}$, the notion of quantum Schubert positivity was used. In general quantum Schubert positivity is possibly weaker than affine Schubert positivity. It follows from [36] that the notions coincide in type A, and we verify that they coincide in type C in Appendix A.

The notion of Mirković-Vilonen positivity does not appear to have been studied in the literature before. We note that the MV-basis is expected to coincide with Lusztig’s semicanonical basis which is distinct from the canonical basis used in Lusztig’s approach to total positivity. So the coincidence $X_{MV}^{>0} = X_{>0}$ might not be immediately expected. As for the comparison $X_{MV}^{>0} = X_{a>0}$ we note that the classes of MV-cycles span $H_*(\text{Gr}_G)$ over $\mathbb{C}$, but the $\mathbb{Z}$-lattice spanned by MV-cycles is known to be strictly contained in the lattice spanned by the Schubert basis.

Our second main theorem (Theorem 7.3) is a parametrization of the totally positive $X_{>0}$ and totally nonnegative $X_{\geq 0}$ parts of $X$. We show that they are homeomorphic to $\mathbb{R}_{>0}$ and $\mathbb{R}_{\geq 0}$ respectively. This was conjectured by the second author in [36] where it was established in type $A$. In type $A_n$ we have that $X = G_P$ is the $n$-dimensional subgroup of lower-triangular unipotent Toeplitz matrices, and thus the parametrization $X_{>0} \simeq \mathbb{R}_{>0}$ is a “finite-dimensional” analogue of the Edrei-Thoma theorem [9] parametrizing infinite totally nonnegative Toeplitz matrices, appearing in the classification of the characters of the infinite symmetric group. The results of this article give an arbitrary type generalization.

The strategy of our proof is as follows: to show that $X_{a>0}^\mathfrak{A} \subseteq X_{MV}^{>0}$ we use a result of Kumar and Nori [24] stating that effective classes in $H_*(\text{Gr}_G)$ are Schubert-positive. We then use the geometric Satake correspondence [13, 30, 26] to describe $X_{MV}^{>0}$ via matrix coefficients, and a result of Berenstein-Zelevinsky [2] to connect to the totally positive part $X_{>0}$.

Finally, to connect $X_{>0}$ back to $X_{a>0}^\mathfrak{A}$, we parametrize the latter directly by combining the positivity of the 3-point Gromov-Witten invariants of $qH^*(G/B)$ with the Perron-Frobenius theorem. This argument follows the strategy of [36].

There is a general phenomenon [27, 2] that totally positive parts have “nice parametrizations”. This phenomenon is closely related to the relation between total positivity and the canonical bases [28], and also the cluster algebra structures on related stratifications [10]. Indeed our work suggests that the coordinate ring $O(X)$ has the affine homology Schubert basis $\{\xi_w\}$ as a “dual canonical basis”, and that the Hopf-dual universal enveloping algebra $U(\mathfrak{g}_P^\vee)$ has the cohomology affine Schubert basis $\{\xi_w^e\}$ as a “canonical basis”. Certainly the affine Schubert bases have the positivity properties expected of canonical bases.

In [37] the type A parametrization result for the totally positive part $X_{>0}$ of the Toeplitz matrices $X$ is proved in a completely different way, using a mirror symmetric construction of $X$. This approach does not however prove the interesting positivity properties of the bases we study in this paper. The mirror symmetric approach was partly generalized to other types in [39], where the existence of a totally positive point in $X$ for any choice of positive quantum parameters is proved (but not its uniqueness). Since the first posting of the present paper two other related papers have appeared. Namely the uniqueness property of the totally positive critical point in the $G/B$ case has been verified by Reda Chhaibi [6], completing the alternative (mirror symmetric) proof of [39] for the parametrization result in...
that case. Moreover, the construction from [37] of a unique positive critical point for a mirror Laurent polynomial was generalized and applied in the context of toric Fano varieties by Sergey Galkin in [12].

Acknowledgements. The authors would like to thank Dale Peterson for his beautiful results which underly this work. The second author also thanks Dima Panov for some helpful conversations. The authors thank Victor Ginzburg for a question which led to the inclusion of Section 6.2.

2. Preliminaries and notation

Let $G$ be a simple linear algebraic group over $\mathbb{C}$ split over $\mathbb{R}$. Usually $G$ will be simply connected. Denote by $\text{Ad} : G \rightarrow GL(\mathfrak{g})$ the adjoint representation of $G$ on its Lie algebra $\mathfrak{g}$. We fix opposite Borel subgroups $B^+$ and $B^-$ defined over $\mathbb{R}$ and intersecting in a split torus $T$. Their Lie algebras are denoted by $\mathfrak{b}^+$ and $\mathfrak{b}^-$ respectively. We will also consider their unipotent radicals $U^+$ and $U^-$ with their Lie algebras $\mathfrak{u}^+$ and $\mathfrak{u}^-$. We use the notations $B^\pm_R, B^\pm_U, U^+_R, U^-_R$ to denote real points.

Let $X^*(T)$ be the character group of $T$ and $X_*(T)$ the group of cocharacters together with the usual perfect pairing $\langle \cdot, \cdot \rangle : X^*(T) \times X_*(T) \rightarrow \mathbb{Z}$. We may identify $X^*(T)$ with a lattice inside $\mathfrak{h}^*$, and $X_*(T)$ with the dual lattice inside $\mathfrak{h}$. These span the real forms $\mathfrak{h}^*_R$ and $\mathfrak{h}_R$, respectively.

Let $\Delta_+ \subset X^*(T)$ be the set of positive roots corresponding to $\mathfrak{b}^+$, and $\Delta_-$ the set of negative roots. There is a unique highest root in $\Delta_+$ which is denoted by $\theta$. Let $I = \{1, \ldots, n\}$ be an indexing set for the set $\Pi := \{\alpha_i \mid i \in I\}$ of positive simple roots. The $\alpha_i$-root space $\mathfrak{g}_{\alpha_i} \subset \mathfrak{g}$ is spanned by Chevalley generator $e_i$ and $\mathfrak{g}_{-\alpha_i}$ is spanned by $f_i$. The split real form of $\mathfrak{g}$, denoted $\mathfrak{g}_R$ is generated by the Chevalley generators $e_i, f_i$.

Let $Q := \langle \alpha_1, \ldots, \alpha_n \rangle_\mathbb{Z}$ be the root lattice. We also have the fundamental weights $\omega_1, \ldots, \omega_n$, and the weight lattice $L := \langle \omega_1, \ldots, \omega_n \rangle_\mathbb{Z}$ associated to $G$. If $G$ is simply connected, we have the relations

$$Q \subset X^*(T) = L \subset \mathfrak{h}^*.$$  

Let $Q^\vee$ denote the lattice spanned by the simple coroots, $\alpha_1^\vee, \ldots, \alpha_n^\vee$, and $L^\vee$ the lattice spanned by the fundamental coweights $\omega_1^\vee, \ldots, \omega_n^\vee$. Then $Q^\vee$ is the dual lattice to $L$ and $L^\vee$ the dual lattice to $Q$, giving

$$Q^\vee = X_*(T) \subset L^\vee \subset \mathfrak{h},$$

in the case where $G$ is simply connected. We set $\rho = \sum_{i \in I} \omega_i$ and write $\text{ht}(\lambda^\vee) = \langle \rho, \lambda^\vee \rangle$ for the height of $\lambda^\vee \in Q^\vee$.

For any Chevalley generator $e_i, f_i$ of $\mathfrak{g}$ we may define a ‘simple root subgroup’ by

$$x_i(t) = \exp(te_i), \quad y_i(t) = \exp(tf_i), \quad \text{for } t \in \mathbb{C}.$$  

Let $W = N_G(T)/T$ be the Weyl group of $G$. It is generated by simple reflections $s_1, \ldots, s_n$. The length function $\ell : W \rightarrow \mathbb{N}$ gives the length of a reduced expression of $w \in W$ in the simple reflections. The unique longest element is denoted $w_0$, and for a root $\alpha$, we let $r_\alpha$ denote the corresponding reflection. For any simple reflection $s_i$ we choose a representative $\hat{s}_i$ in $G$ defined by

$$\hat{s}_i := x_i(-1)y_i(1)x_i(-1).$$
If \( w = s_{i_1} \ldots s_{i_m} \) is a reduced expression, then \( \dot{w} := \dot{s}_{i_1} \ldots \dot{s}_{i_m} \) is a well-defined representative for \( w \), independent of the reduced expression chosen. \( W \) is a poset under the Bruhat order \( \leq \).

We denote the Langlands dual group of \( G \) by \( G^\vee \), or \( G^\vee_C \) to emphasize that we mean the algebraic group over \( \mathbb{C} \). The notations for \( G^\vee \) are the same as those for \( G \) but with added \( ^\vee \) and any other superscripts moved down, for example \( B^\vee \) for the analogue of \( B^+ \).

2.1. Parabolic subgroups. Let \( P \) denote a parabolic subgroup of \( G \) containing \( B^+ \), and let \( p \) be the Lie algebra of \( P \). Let \( I_P \) be the subset of \( I \) associated to \( P \) consisting of all the \( i \in I \) with \( \dot{s}_i \in P \) and consider its complement \( I^P := I \setminus I_P \).

Associated to \( P \) we have the parabolic subgroup \( W_P = \langle s_i \mid i \in I_P \rangle \) of \( W \). We let \( W^P \subset W \) denote the set of minimal coset representatives for \( W/W_P \). An element \( w \) lies in \( W^P \) precisely if for all reduced expressions \( w = s_{i_1} \ldots s_{i_m} \) the last index \( i_m \) always lies in \( I^P \). We write \( w^P \) or \( w_0^P \) for the longest element in \( W^P \), while the longest element in \( W_P \) is denoted \( w_P \). For example \( w_0^B = w_0 \) and \( w_B = 1 \). Finally \( P \) gives rise to a decomposition

\[
\Delta_+ = \Delta_{P,+} \sqcup \Delta^P_+.
\]

Here \( \Delta_{P,+} = \{ \alpha \in \Delta_+ \mid \langle \alpha, \omega_i^\vee \rangle = 0 \text{ all } i \in I^P \} \), so that

\[
p = b^+ \oplus \bigoplus_{\alpha \in \Delta_{P,+}} g_{-\alpha},
\]

and \( \Delta^P_+ \) is the complement of \( \Delta_{P,+} \) in \( \Delta_+ \). For example \( \Delta_{B,+} = \emptyset \) and \( \Delta^B_+ = \Delta_+ \).

3. Total positivity.

3.1. Total positivity. A matrix \( A \) in \( GL_n(\mathbb{R}) \) is called totally positive (or totally nonnegative) if all the minors of \( A \) are positive (respectively nonnegative). In other words \( A \) acts by positive or nonnegative matrices in all of the fundamental representations \( \Lambda^\pm \mathbb{R}^n \) (with respect to their standard bases). In the 1990’s Lusztig [27] extended this theory dating back to the 1930’s to all reductive algebraic groups. This work followed his construction of canonical bases and utilized their deep positivity properties in types ADE.

Let \( G \) be a simple algebraic group, split over \( \mathbb{R} \), not assumed to be simply connected for the purposes for this section. The definitions and results here are formulated for a general such group \( G \), but will later on be applied to the group we have denoted by \( G^\vee \).

Definition 3.1. The totally nonnegative part \( U^+_{\geq 0} \) of \( U^\pm_{\mathbb{R}} \) is defined to be the semigroup generated by \( \{ x_i(t) \mid i \in I \text{ and } t \in \mathbb{R}_{\geq 0} \} \). Similarly the totally nonnegative part \( U^-_{\geq 0} \) of \( U^-_{\mathbb{R}} \) is the semigroup generated by \( \{ y_i(t) \mid i \in I \text{ and } t \in \mathbb{R}_{\geq 0} \} \). The totally positive parts are given by \( U^+_0 = U^+_\mathbb{R} \cap B^- \dot{w}_0 B^- \) and \( U^-_0 = U^-_{\mathbb{R}} \cap B^+ \dot{w}_0 B^+ \).

3.2. Matrix coefficients. Suppose \( \lambda \in X^*(T) \) is dominant. Then we have a highest weight irreducible representation \( V_\lambda \) for \( G \). The Lie algebra \( g \) also acts on \( V_\lambda \) as does its universal enveloping algebra \( U(g) \). We fix a highest weight vector \( v^\lambda_+ \) in \( V_\lambda \). The vector space \( V_\lambda \) has a real form given by \( V_{\lambda,\mathbb{R}} = U(g_{\mathbb{R}}) \cdot v^\lambda_+ \).

Let \( (\cdot)^T : U(g) \to U(g) \) be the unique involutive anti-automorphism satisfying \( e_i^T = f_i \). We let \( \langle \cdot, \cdot \rangle : V_\lambda \times V_\lambda \to \mathbb{C} \) denote the unique symmetric, non-degenerate
bilinear form (Shapovalov form) [23, II, 2.3] satisfying
\[ \langle u \cdot v, v' \rangle = \langle v, u^T \cdot v' \rangle \quad \text{for all } u \in U(\mathfrak{g}), v, v' \in V_{\lambda}, \] (3.1)
normalized so that \( \langle v^+_\lambda, v^+_\lambda \rangle = 1 \). The Shapovalov form is real positive definite on \( V_{\lambda,R} \), see [23, Theorem 2.3.13].

We will be studying total positivity in the Langlands dual group of a simply-connected group. Thus in our application the group will be adjoint. Let \( G_{sc} \) be the simply-connected cover of the general complex simple algebraic group \( G \). Then the unipotent subgroups of \( G_{sc} \) and \( G \) can be identified, and so can their totally positive (resp. negative) parts. The purpose of this observation is to allow the evaluation of matrix coefficients of fundamental representations on the unipotent subgroups of \( G \). (As opposed to \( G_{sc} \), the group \( G \) itself may not act on these representations.)

Thus for a fundamental weight \( \omega_i \) (not necessarily a character of \( G \!\) ) and a vector \( v \) in the fundamental representation \( V_{\omega_i} \) of \( g \) we have a matrix coefficient
\[
y \mapsto \langle v, y \cdot v + \omega_i \rangle
\]
defined for \( y \in U^− \). The following result follows from a theorem ([2, Theorem 1.5]) of Berenstein and Zelevinsky (note that every chamber weight is a \( w_0 \)-chamber weight in the terminology of [2]).

**Proposition 3.2.** Let \( y \in U_{R}^− \). Then \( y \) is totally positive if and only if for all \( i \in I \) and \( w \in W \) we have
\[
\langle w \cdot v^+_\omega_i, y \cdot v^+_\omega_i \rangle > 0,
\]
where the matrix coefficient is as defined above.

We will need the following variation on the above Proposition.

**Proposition 3.3.** Let \( y \in U_{R}^− \). Suppose that for all irreducible representations \( V_{\lambda} \) of \( G \) it holds that
\[ \langle v, y \cdot v^+_\lambda \rangle > 0, \] (3.2)
for some choice of highest weight vector \( v^+_\lambda \) and any weight vector \( v \) satisfying the following two conditions.

- The vector \( v \) lies in a one-dimensional weight space of the real form \( V_{\lambda,R} \).
- \( \langle v, x \cdot v^+_\lambda \rangle > 0 \) for all totally positive \( x \in U^−_{>0} \).

Then \( y \) is totally positive.

The proof of Proposition 3.3 is delayed until Section 13. If \( G \) is simply connected then this Proposition 3.3 follows from Proposition 3.2. The difference arises if \( G \) is not simply connected, in which case the fundamental weights will not all be characters of the maximal torus of \( G \), so that we may not be able to take \( \lambda \) to be \( \omega_i \).

**Remark 3.4.** Suppose \( G \) is simply-laced. Then the matrix coefficients of \( x \in U^−_{>0} \) in the canonical basis of any irreducible representation \( V_{\lambda} \) are positive. It follows that for any \( v \neq 0 \) lying in a one-dimensional weight space of \( V_{\lambda,R} \), either \( v \) or \(-v\) has the property that \( \langle v, x \cdot v^+_\lambda \rangle > 0 \) for all \( x \in U^−_{>0} \).
4. THE AFFINE GRASSMANNIAN AND GEOMETRIC SATAKE

In this section, $G$ is a simple simply-connected linear algebraic group over $\mathbb{C}$. Let $\mathcal{O} = \mathbb{C}[[t]]$ denote the ring of formal power series and $\mathcal{K} = \mathbb{C}((t))$ the field of formal Laurent series. Let $\text{Gr}_G = G(\mathcal{K})/G(\mathcal{O})$ denote the affine Grassmannian of $G$.

4.1. Affine Weyl group. Let $W_{af} = W \ltimes X_*(T)$ be the affine Weyl group of $G$. For a cocharacter $\lambda \in X_*(T)$ we write $t_\lambda \in W_{af}$ for the translation element of the affine Weyl group. We then have the commutation formula $wt_\lambda w^{-1} = t_{w_\lambda}$.

The affine Weyl group is also a Coxeter group, generated by simple reflections $s_0, s_1, \ldots, s_n$, where $s_0 = r_\rho l_{\rho'}$. It is a graded poset with its usual length function $\ell : W_{af} \to \mathbb{Z}_{\geq 0}$, and Bruhat order $\geq$.

Let $W^-_{af}$ denote the minimal length coset representatives of $W_{af}/W$. Thus we have canonical bijections

\begin{equation}
X_*(T) \leftrightarrow W_{af}/W \leftrightarrow W^-_{af},
\end{equation}

The intersection $X_*(T) \cap W^-_{af}$ is given by the anti-dominant translations, that is $t_\lambda$ where $\langle \alpha_i, \lambda \rangle \leq 0$ for each $i \in I$.

Note that an element of $X_*(T)$ viewed as a map from $\mathbb{C}^*$ to $T$ can also be reinterpreted as an element of $T(\mathcal{K})$. We denote this element by $t^\lambda$. The two should not be confused since the isomorphism $W_{af} \to N_{G(\mathcal{K})}(T)/T$ sends $t_\lambda$ to $t^{-\lambda}$.

4.2. Geometric Satake and Mirković-Vilonen cycles. The affine Grassmannian is an ind-scheme [26], see also [23]. The $G(\mathcal{O})$-orbits $\text{Gr}_\lambda$ on $\text{Gr}_G$ are parametrized by the dominant cocharacters $\lambda \in X_+^* (T)$. Namely,

$$\text{Gr}_\lambda := G(\mathcal{O}) t^\lambda G(\mathcal{O}) / G(\mathcal{O}).$$

The geometric Satake correspondence [13, 26, 30] states that the tensor category $\text{Perv}(\text{Gr}_G)$ of $G(\mathcal{O})$-equivariant perverse sheaves on $\text{Gr}_G$ with $\mathbb{C}$-coefficients is equivalent to the tensor category $\text{Rep}(G^G_v)$ of finite-dimensional representations of the Langlands dual group $G^G_v$. (For our purposes the tensor structure will be unimportant.) The simple objects of $\text{Perv}(\text{Gr}_G)$ are the intersection cohomology complexes $IC_\lambda$ of the $G(\mathcal{O})$-orbit closures $\text{Gr}_\lambda$. They correspond under the geometric Satake correspondence to the highest weight representations $V_\lambda$ of $G^G_v$. Furthermore, we have a canonical isomorphism

\begin{equation}
IH^*(\text{Gr}_\lambda) \cong H^*(\text{Gr}_G, IC_\lambda) \cong V_\lambda.
\end{equation}

Mirković and Vilonen found explicit cycles in $\text{Gr}_G$ whose intersection homology classes give rise to a weight-basis of $V_\lambda$ under the isomorphism (4.2). We denote by $\text{MV}_\lambda, v$ the MV-cycle with corresponding basis vector $v \in V_\lambda$. For $w \in W$, the weight-space $V_\lambda (w\lambda)$ is one-dimensional. We denote by $\text{MV}_{\lambda, w\lambda}$ the corresponding MV-cycle. Thus $[\text{MV}_{\lambda, w\lambda}]_{IH} \in IH^*(\text{Gr}_\lambda) \cong V_\lambda$ has weight $w\lambda$. All the statements of this section hold with $\mathbb{R}$-coefficients: we take perverse sheaves with $\mathbb{R}$-coefficients, and consider the representations of a split real form $G^G_v$ of the Langlands dual group.

4.3. Schubert varieties in $\text{Gr}_G$. Let $\mathcal{I} \subset G(\mathcal{O})$ denote the Iwahori subgroup of elements $g(t)$ which evaluate to $g \in B^\pm$ at $t = 0$. The $\mathcal{I}$-orbits $\Omega_\mu$ on $\text{Gr}_G$, called Schubert cells, are labeled by all (not necessarily dominant) cocharacters $\mu \in X_*(T)$. Explicitly,

$$\Omega_\mu = \mathcal{I} t^\mu G(\mathcal{O}) / G(\mathcal{O}).$$
Alternatively, we may label Schubert cells by cosets \( xW \in W_{af}/W \) or minimal coset representatives \( x \in W_{af}^- \), using the bijection (4.1). Choosing a representative \( \dot{x} \) of \( x \) we have

\[
\Omega_x = \mathcal{T}_{\dot{x}}G(O)/G(O).
\]

The Schubert cell \( \Omega_x = \Omega_{\dot{x}} \) is isomorphic to \( \mathbb{C}^{\ell(x)} \) whenever \( x \in W_{af}^- \). We note that \( \Omega_\mu = \Omega_{\lambda,\mu} \) if \( \mu \) is dominant, compare Section 4.1. The Schubert varieties \( X_\mu = \Omega_\mu \), alternatively denoted \( X_\mu = \Omega_{\mu} \), are themselves unions of Schubert cells: \( X_x = \sqcup_{v \leq x} \Omega_v \). The \( G(O) \) orbits are also unions of Schubert cells:

\[
\text{Gr}_\lambda = \bigsqcup_{w \in W} \Omega_{w,\lambda}.
\]

In particular the largest one of these, \( \Omega_\lambda \equiv \mathbb{C}^{\ell(t_{-\lambda})} \), is open dense in \( \text{Gr}_\lambda \) (where we assumed \( \lambda \) dominant), and so

\[
\overline{\text{Gr}_\lambda} = \overline{\Omega_\lambda} = X_\lambda.
\]

Thus every \( G(O) \)-orbit closure is a Schubert variety, but not conversely. Moreover \( \text{Gr}_\lambda \) has dimension \( \ell(t_{-\lambda}) \), which equals \( 2 \cdot \text{ht}(\lambda) \).

We note that the \( MV \)-cycle \( MV_{\lambda,v} \) is an irreducible subvariety of \( \overline{\text{Gr}_\lambda} \) of dimension \( \text{ht}(\lambda) + \text{ht}(\nu) \) if \( \nu \) lies in the \( \nu \)-weight space of \( V_\lambda \), see [30, Theorem 3.2]. In particular \( MV_{\lambda,\lambda} = \text{Gr}_\lambda \) and \( MV_{\lambda,\nu,\lambda} \) is just a point.

4.4. The (co)homology of \( \text{Gr}_G \). The space \( \text{Gr}_G \) is homotopy equivalent to the based loop group \( \Omega K \) of continuous maps of \( S^1 \) into the compact form \( K \subset G \) [34, 33] (see [31] for a discussion of this). Thus the homology \( H_*(\text{Gr}_G; \mathbb{C}) \) and cohomology \( H^*(\text{Gr}_G; \mathbb{C}) \) are commutative and co-commutative graded dual Hopf algebras over \( \mathbb{C} \).

Ginzburg [13] (see also [3]) and Dale Peterson [32] described \( H_*(\text{Gr}_G; \mathbb{C}) \) as the coordinate ring of the stabilizer subgroup of a principal nilpotent in \( (g^\lambda)^* \). Namely, in our conventions, let \( F \in (g^\mu)^* \) be the principal nilpotent element defined by

\[
F = \sum_{i \in I} (e_i^\nu)^*,
\]

where \( (e_i^\nu)^*(\zeta) = 0 \) if \( \zeta \in g_\alpha^\vee \) for \( \alpha \neq \alpha_i \), and \( (e_i^\nu)^*(e_i^\nu) = 1 \). Let \( X = (G^\lambda)^F \) denote the stabilizer of \( F \) inside \( G^\lambda \), under the coadjoint action. It is an abelian subgroup of \( U_{\lambda}^\vee \) of dimension equal to the rank of \( G \). Then the result from [13, 32] says that \( H_*(\text{Gr}_G) \) is Hopf-isomorphic to the ring of regular functions on \( X \). Moreover, the cohomology, \( H^*(\text{Gr}_G, \mathbb{C}) \) is Hopf-isomorphic to the universal enveloping algebra \( U(g_{\lambda}^\vee) \) of the centralizer of \( F \), as graded dual.

We note that Ginzburg [13] works over \( \mathbb{C} \) while Peterson [32] works over \( \mathbb{Z} \), but the details of Peterson’s work are so far unpublished. Another approach is given in work of Yun and Zhu [41].

Our choice of principal nilpotent \( F \) is compatible via Peterson’s isomorphism (6.3), see [25], with the conventions in [21, 22, 38], and is related to the choice in [13, 32] by switching the roles of \( B^+ \) and \( B^- \).

In terms of the above presentation of \( H_*(\text{Gr}_G) \), the fundamental class of an MV-cycle can be described as follows. Let \( \langle ., . \rangle : H^*(\text{Gr}_G) \times H_*(\text{Gr}_G) \rightarrow \mathbb{C} \) be the pairing obtained from cap product composed with pushing forward to a point.
Proposition 4.1. Suppose MV\(_{\lambda,v}\) is the MV-cycle with corresponding weight vector \(v \in V_\lambda\) under (4.2). Let \(u \in U(\mathfrak{g}_F^+) \simeq H^*(\text{Gr}_G)\). Then the fundamental class \([\text{MV}_{\lambda,v}] \in H_*(\text{Gr}_G)\) satisfies
\[
\langle u, [\text{MV}_{\lambda,v}] \rangle = \langle u \cdot v, v^- - \lambda \rangle,
\]
where \(v^-\) is the lowest weight vector of \(V_\lambda\) (in the MV-basis).

Proof. The argument is essentially the same as [13, Proposition 1.9] (see also [14, 15]); the main difference is that in our conventions \(u\) is lower unipotent, rather than upper unipotent, however accordingly \(\text{Gr}_\lambda\) is in our conventions the MV-cycle representing the highest weight vector, whereas it is the lowest weight vector in [13]. So the difference is that everywhere the roles of \(B^+\) and \(B^-\) are interchanged. By [13, Theorem 1.7.6], the action of \(u \in U(\mathfrak{g}_F^+)\) on \(V_\lambda\) is compatible with the action of the corresponding element in \(H^*(\text{Gr}_G)\) on \(H^*(\text{Gr}_\lambda)\). Under (4.2), the vector \(v\) is sent to \([\text{MV}_{\lambda,v}]\) which maps to the fundamental class \([\text{MV}_{\lambda,v}]\) under the natural map from the intersection cohomology \(H_*(\text{Gr}_\lambda)\) to the homology \(H_*(\text{Gr}_\lambda)\). Finally, pushing forward to a point is the same as pairing with \(v^-\) (in our conventions). So we get the identity
\[
\langle u, [\text{MV}_{\lambda,v}] \rangle = \pi^*(u \cap [\text{MV}_{\lambda,v}]) = \langle v^-, u \cdot v \rangle,
\]
where \(\pi : X \to \{pt\}\). \(\square\)

4.5. Schubert basis. We have
\[
H_*(\text{Gr}_G) = \bigoplus_{x \in W^-_{af}} \mathbb{C} \cdot \xi_x, \quad H^*(\text{Gr}_G) = \bigoplus_{x \in W^-_{af}} \mathbb{C} \cdot \xi^x,
\]
where the \(\xi_x\) are the fundamental classes \([X_w]\) of the Schubert varieties, and \(\{\xi^w\}\) is the cohomology basis (dual under the cap product). Suppose \(\lambda\) is dominant, then we also have
\[
H_*(\text{Gr}_\lambda) = \bigoplus_{x \in W^-_{af}, x \leq t^-_{\lambda}} \mathbb{C} \cdot \xi_x,
\]
because of (4.3) and the decomposition of \(X_\lambda\) into Schubert cells.

By Ginzburg/Peterson’s isomorphism, we will often think of a Schubert basis element \(\xi_w\) as a function on \(X\). The Schubert basis of \(H_*(\text{Gr}_G)\) has the following factorization property:

Proposition 4.2 ([32][25, Proposition 9.1]). Suppose \(wt_\nu, t_\mu \in W^-_{af}\). Then \(\xi_{wt_\nu}t_\mu = \xi_{wt_\nu}t_\mu\).

We remark that if \(wt_\nu \in W^-_{af}\), then necessarily \(\nu\) is anti-dominant.

5. The Quantum Cohomology Ring of \(G/P\)

5.1. The usual cohomology of \(G/P\) and its Schubert basis. For our purposes it will suffice to take homology or cohomology with complex coefficients, so \(H^*(G/P)\) will stand for \(H^*(G/P, \mathbb{C})\). By the well-known result of C. Ehresmann, the singular homology of \(G/P\) has a basis indexed by the elements \(w \in W^P\) made up of the fundamental classes of the Schubert varieties,
\[
X^P_w := (B^wP/P) \subseteq G/P.
\]
Here the bar stands for (Zariski) closure. Let \( \sigma^P_w \in H^*(G/P) \) be the Poincaré dual class to \([X^P_w]\). Note that \( X^P_w \) has complex codimension \( \ell(w) \) in \( G/P \) and hence \( \sigma^P_w \) lies in \( H^{2\ell(w)}(G/P) \). The set \( \{ \sigma^P_w \mid w \in W^P \} \) forms a basis of \( H^*(G/P) \) called the Schubert basis. The top degree cohomology of \( G/P \) is spanned by \( \sigma^P_w \), and we have the Poincaré duality pairing

\[
H^*(G/P) \times H^*(G/P) \longrightarrow \mathbb{C}, \quad (\sigma, \mu) \mapsto \langle \sigma \cup \mu \rangle
\]

which may be interpreted as taking \( (\sigma, \mu) \) to the coefficient of \( \sigma^P_w \) in the basis expansion of the product \( \sigma \cup \mu \). For \( w \in W^P \) let \( PD(w) \in W^P \) be the minimal length coset representative in \( w_0 w W^P \). Then this pairing is characterized by

\[
\langle \sigma^P_w \cup \sigma^P_v \rangle = \delta_{w, PD(v)}.
\]

5.2. The quantum cohomology ring \( qH^*(G/P) \). The (small) quantum cohomology ring \( qH^*(G/P) \) is a deformation of the usual cohomology ring by \( \mathbb{C}[q^P_1, \ldots, q^P_k] \), where \( k = \dim H^2(G/P) \), with structure constants defined by 3-point genus 0 Gromov-Witten invariants. For more background on quantum cohomology, see [11].

We have

\[
qH^*(G/P) = \bigoplus_{w \in W^P} \mathbb{C}[q^P_1, \ldots, q^P_k] \cdot \sigma^P_w
\]

where \( \sigma^P_w \) now (and in the rest of the paper) denotes the quantum Schubert class. The quantum cup product is defined by

\[
\sigma^P_v \cdot \sigma^P_w = \sum_{d \in \mathbb{N}^k} \langle \sigma^P_u, \sigma^P_v, \sigma^P_w \rangle_d q^d \sigma^P_{PD(u)}
\]

where \( q^d \) is multi-index notation for \( \prod_{i=1}^k q^d_i \), and the \( \langle \sigma^P_u, \sigma^P_v, \sigma^P_w \rangle_d \) are genus 0, 3-point Gromov-Witten invariants. These enumerate rational curves in \( G/P \), with a fixed degree determined by \( d \), which pass through general translates of three Schubert varieties. In particular, \( \langle \sigma^P_v, \sigma^P_u, \sigma^P_w \rangle_d \) is a nonnegative integer.

The quantum cohomology ring \( qH^*(G/P) \) has an analogue of the Poincaré duality pairing which may be defined as the symmetric \( \mathbb{C}[q^P_1, \ldots, q^P_k] \)-bilinear pairing

\[
qH^*(G/P) \times qH^*(G/P) \longrightarrow \mathbb{C}[q^P_1, \ldots, q^P_k], \quad (\sigma, \mu) \mapsto \langle \sigma \cdot \mu \rangle_q
\]

where \( \langle \sigma \cdot \mu \rangle_q \) denotes the coefficient of \( \sigma^P_w \) in the Schubert basis expansion of the product \( \sigma \cdot \mu \). In terms of the Schubert basis the quantum Poincaré duality pairing on \( qH^*(G/P) \) is given by

\[
\langle \sigma^P_v \cdot \sigma^P_w \rangle_q = \langle \sigma^P_w \cup \sigma^P_v \rangle = \delta_{w, PD(v)},
\]

where \( v, w \in W^P \), and \( PD : W^P \to W^P \) is the involution defined in Section 5.1. Equation (5.1) is a consequence of properties of the small quantum cup product, see [8, Proposition 8.1.6].

6. Peterson’s theory

In this section we summarize Peterson’s results concerning his geometric realizations of \( qH^*(G/P) \) and their relationship with \( H_*(\text{Gr}_G) \).
6.1. **Definition of the Peterson variety.** Each $\text{Spec}(qH^\ast(G/P))$ turns out to be most naturally viewed as lying inside the Langlands dual flag variety $G^\vee/B^\vee$, where it appears as a stratum (non-reduced intersection with a Bruhat cell) of one $n$-dimensional projective variety called the **Peterson variety**. This remarkable fact was discovered and shown by Dale Peterson [32].

Recall the definition of $F \in (\mathfrak{g}^\vee)^\ast$ from Section 4.4. The condition

$$(\text{Ad}(g^{-1}) \cdot F)(X) = 0 \text{ for all } X \in [u^\vee, u^\vee],$$

defines a closed subvariety of $G^\vee$ invariant under right multiplication by $B^\vee$. Thus it defines a closed subvariety of $G^\vee/B^\vee$. This subvariety $\mathcal{Y}$ is the **Peterson variety** for $G$. Explicitly we have

$$\mathcal{Y} = \{gB^\vee \in G^\vee/B^\vee \mid \text{Ad}(g^{-1}) \cdot F \in [u^\vee, u^\vee]^\perp\}.$$

For any parabolic subgroup $W_P \subset W$ with longest element $w_P$ define $\mathcal{Y}_P$ as non-reduced intersection,

$$\mathcal{Y}_P := \mathcal{Y} \times_{G^\vee/B^\vee} (B^\vee_P w_P B^\vee_P/B^\vee_P).$$

**Remark 6.1.** For $P = B$ we have a map

$$\mathcal{Y}_B \rightarrow \mathcal{A}_G : \quad uB^\vee \mapsto u^{-1} \cdot F,$$

where $\mathcal{A}_G \subset (\mathfrak{g}^\vee)^\ast$ is the degenerate leaf of the Toda lattice. This map is an isomorphism as follows from classical work of Kostant [20]. Kostant also showed that $\mathcal{Y}_B$ is irreducible [21].

The isomorphism between $qH^\ast(G/B)$ and the functions on the degenerate leaf of the Toda lattice was established by B. Kim [18] building on [16].

6.2. **Irreducibility of $\mathcal{Y}$.** It is not immediately obvious from the above definition that the Peterson variety $\mathcal{Y}$ is irreducible. In other words apart from the closure of $\mathcal{Y}_B$ it could a priori contain some other irreducible components coming from intersections with other Bruhat cells. We include a sketch of proof (put together from [32]) that this doesn’t happen, and that therefore $\mathcal{Y}$ is irreducible, $n$-dimensional and equal to the closure of $\mathcal{Y}_B$. Namely we have the following proposition.

**Proposition 6.2** (Dale Peterson). If $w = w_P$, the longest element in $W_P$ for some parabolic subgroup $P$, then $\mathcal{Y} \cap B^\vee w B^\vee /B^\vee$ is nonempty and of dimension $|P|$. Otherwise $w^{-1} \cdot (-\Pi^\vee) \not\subset \Delta^\vee \cup \Pi^\vee$ and $\mathcal{Y} \cap B^\vee w B^\vee /B^\vee = \emptyset$.

**Sketch of proof.** Clearly $w^{-1} \cdot F$ needs to lie in $b_1 := [u^\vee, u^\vee]^\perp$ for $\mathcal{Y} \cap B^\vee_P w B^\vee /B^\vee$ to be non-empty. So $w^{-1} \cdot (-\Pi^\vee) \subset \Delta^\vee \cup \Pi^\vee$. This is the case if and only if $w = w_P$ for some parabolic $P$, by a lemma from [32] reproduced in [35, Lemma 2.2].

Consider the map

$$\psi : (U^+)^\vee \rightarrow (u^\vee)^\ast,$$

$$u \mapsto (u^{-1} \cdot F)|_{u^\vee}.$$

The coordinate rings of $(U^+)^\vee$ and $(u^\vee)^\ast$ are polynomial rings. On $(U^+)^\vee$ consider the $\mathbb{C}^\ast$-action coming from conjugation by the one-parameter subgroup of $T^\vee$ corresponding to $\rho \in X_\rho(T^\vee)$. On $(u^\vee)^\ast$ let $\mathbb{C}^\ast$ act by $z \cdot X_\alpha = z^{\alpha,\rho > +1} X_\alpha$ for $X_\alpha$ in the $\alpha$-weight space of $(u^\vee)^\ast$ and $\alpha \in \Delta^\vee_+$. Then $\psi^\ast$ is a homomorphism of (positively) graded rings, namely it is straightforward to check that $\psi$ is $\mathbb{C}^\ast$-equivariant.
Also \( \psi^{-1}(0) = \{0\} \), in terms of \( \mathbb{C} \)-valued points or indeed over any algebraically closed field. Peterson proves this in [32] by considering the \( \mathcal{B}_-^- \)-Bruhat decomposition intersected with \( U_\nu^- \). Namely, the only way \( \psi(u) \) can be 0 for \( u \in U_\nu^- \cap \mathcal{B}_-^- \) \( \mathcal{B}_-^- \) is if \( w = e \), wherefore \( u \) must be the identity element in \( U_\nu^- \).

It follows from these two properties that \( \psi \) is finite. For example by page 660 in Griffiths-Harris and using the \( \mathbb{C}^* \)-action to go from the statement locally around zero, to a global statement, or by another proposition in Peterson’s lectures [32].

Let

\[
U_P := \psi^{-1}((w_P \cdot b_\Pi)|_{u^-}) = \{ u \in U_\nu^- \mid (u^{-1} \cdot F)|_{u^-} \in (w_P \cdot b_\Pi)|_{u^-} \}.
\]

Since \( u^{-1} \cdot F \in F + \mathfrak{h} + (u^-)^* \) for \( u \in U_\nu^- \) and \( F + \mathfrak{h} \subset w_P \cdot b_\Pi \), we can drop the restriction to \( u^- \) on both sides of the condition above, and we have a projection map

\[
U_P = \{ u \in U_\nu^- \mid u^{-1} \cdot F \in w_P \cdot b_\Pi \} = \{ u \in U_\nu^- \mid w_P^{-1} u^{-1} \cdot F \in b_\Pi \} \to \mathcal{Y} \cap B_\nu^- w_P B_\nu^- / B_\nu^- \to U_P \cap uw_P B_\nu^- ,
\]

which is a fiber bundle with fiber \( \cong \mathbb{C}^{\ell(w_P)} \).

Since \( \psi \) is finite the dimension of \( U_P \) is equal to the dimension of the subspace \( (w_P \cdot b_\Pi)|_{u^-} \) inside \( (u^-)^* \). This dimension is just \( |I_P^+| + \ell(w_P) \), by looking at the weight space decomposition. So \( \mathcal{Y} \cap B_\nu^- w_P B_\nu^- / B_\nu^- \) has dimension \( |I_P| \).

6.3. Geometric realization of \( qH^*(G/P) \). Recall the stabilizer \( X \) of the principal nilpotent \( F \), which is an \( n \)-dimensional abelian subgroup of \( (U^-)^\circ \). Using an idea of Kostant’s [19, page 304], the Peterson variety may also be understood as a compactification of \( X \). Namely,

\[
\mathcal{Y} = \overline{X \tilde{w}_0 B_\nu^- / B_\nu^-} \subset G^\circ / B_\nu^- .
\]

For the parabolic \( P \) let

\[
\mathcal{Y}_P^* := \mathcal{Y}_P \times_{G^\circ / B_\nu^-} X \tilde{w}_0 B_\nu^- / B_\nu^- = (X \times_{G^\circ} B_\nu^- \tilde{w}_P \tilde{w}_0 B_\nu^-) \tilde{w}_0 / B_\nu^- \cong X \times_{G^\circ} B_\nu^- \tilde{w}_P \tilde{w}_0 B_\nu^+ ,
\]

or equivalently,

\[
\mathcal{Y}_P^* = \mathcal{Y}_P \times_{G^\circ / B_\nu^-} B_\nu^- \tilde{w}_P \tilde{w}_0 B_\nu^- / B_\nu^- .
\]

We define

\[
X_P := X \times_{G^\circ} B_\nu^- \tilde{w}_P \tilde{w}_0 B_\nu^+ ,
\]

so that the above is an isomorphism \( \mathcal{Y}_P^* \cong X_P \).

**Theorem 6.3** (Dale Peterson).

1. The \( \mathcal{Y}_P \) give rise to a decomposition

\[
\mathcal{Y}(\mathbb{C}) = \bigsqcup_P \mathcal{Y}_P(\mathbb{C}).
\]

where \( \mathcal{Y}_B(\mathbb{C}) \) is open dense in \( \mathcal{Y}(\mathbb{C}) \).

2. For \( P = B \) we have an isomorphism

\[
\mathcal{P} : qH^*(G/B) \tilde{\sim} \mathcal{O}(\mathcal{Y}_B),
\]

via the isomorphism \( 6.1 \) of \( \mathcal{Y}_B \) with the degenerate leaf of the Toda lattice of \( G^\circ \).
(3) For any Schubert class $\sigma_w$, let $S^w$ denote regular function on $Y_B$ which is the image $\mathcal{P}(\sigma_w)$ of $\sigma_w$ under the isomorphism $\mathcal{P}$ from (6.2). Suppose that $w \in W^P$. Then $S^w$ extends regularly to $Y_P$. In this case, let $S^w_P$ denote the regular function in $\mathcal{O}(Y_P)$ obtained from the extension of $S^w$ by restriction to $Y_P$. There is a (uniquely determined) isomorphism
\[ qH^*(G/P) \cong \mathcal{O}(Y_P) \]
which takes $\sigma_w^P$ to $S^w_P$.

(4) The isomorphisms above restrict, to give isomorphisms
\[ qH^*(G/P)[q_1^{-1}, \ldots, q_k^{-1}] \cong \mathcal{O}(Y^*_P). \]

In particular, Theorem 6.3(1) gives
\[ X(\mathbb{C}) = \bigsqcup_P X_P(\mathbb{C}). \]

6.4. Quantum cohomology and homology of the affine Grassmannian.

**Theorem 6.4** (Dale Peterson).

1. The composition of isomorphisms
\[ H_*(\text{Gr}_G)[\xi_{(t_s)}^{-1}] \cong \mathcal{O}(X_B) \cong \mathcal{O}(Y_B^*) \cong qH^*(G/B)[q_1^{-1}, \ldots, q_n^{-1}] \]
is given by
\[ \xi_{w,t_s}^{-1} \xi_{t_s}^{-1} \mapsto q_{\lambda-\mu}^s \sigma_w^B \]
where $q_\nu = q_1^{a_1} q_2^{a_2} \cdots q_n^{a_n}$ if $\nu = a_1\alpha_1^\vee + \cdots + a_n\alpha_n^\vee$.

2. More generally, for an arbitrary parabolic $P$ the composition
\[ (H_*(\text{Gr}_G)/J_P)[(\xi_{(t_s)}^{-1})] \cong \mathcal{O}(X_P) \cong \mathcal{O}(Y_P^*) \cong qH^*(G/P)[q_1^{-1}, \ldots, q_k^{-1}] \]
is given by
\[ \xi_{w,\pi_P(t_s)}^{-1} \xi_{\pi_P(t_s)}^{-1} \mapsto q_{\eta_P(\lambda-\mu)}^s \sigma_w^P \]
where $J_P \subset H_*(\text{Gr}_G)$ is an ideal, $\pi_P$ maps $W_{af}$ to a subset $(W^P)_{af}$, and $\eta_P$ is the natural projection $Q^\vee \to Q^\vee/Q^\vee_P$ where $Q^\vee_P$ is the root lattice of $W_P$.

The first author and Shimozono [25] verified that the maps (6.4) (resp. (6.6)) are isomorphisms from $H_*(\text{Gr}_G)[\xi_{(t_s)}^{-1}]$ to $qH^*(G/B)[q_1^{-1}, \ldots, q_n^{-1}]$ (respectively from, in the parabolic case, $(H_*(\text{Gr}_G)/J_P)[(\xi_{(t_s)}^{-1})]$ to $qH^*(G/P)[q_1^{-1}, \ldots, q_k^{-1}]$). We do not review the definitions of $J_P$ and $\pi_P$ here, but refer the reader to [25].

**Remark 6.5.** In [25] it is not shown that the isomorphism (6.4) is the one induced by the geometry of $X$. We sketch how this can be achieved.

First, Kostant [21, Section 5] expresses the quantum parameters as certain ratios of ‘chamber minors’ on $X$. Ginzburg’s [13, Proposition 1.9] also expresses the translation affine Schubert classes $\xi_{t-\lambda}$ as matrix coefficients, since $\xi_{t-\lambda} = [X_\lambda] = [\text{Gr}_\lambda] = [MV_{\lambda,\lambda}]$. This allows one to compare $\xi_{t-\lambda}$ with $q_\lambda$ as functions on $X_B$, and see that they agree. Namely both are equal to $x \mapsto \langle x \cdot v_\lambda^+, v_\lambda^+ \rangle$.

Let $\lambda = m\omega_\vee$ be a positive multiple of $\omega_\vee$ contained in $Q^\vee$. We now compare the functions $\xi_{t-\lambda}$ and $q_{-\lambda}^s \sigma_{t-\lambda}$ on $X_B$. For the function $\sigma_{t-\lambda}$, Kostant gives a formula in [21, (119)] as a ratio of matrix coefficients on $X$. For the function $\xi_{t-\lambda}$, one
notes that since \( \lambda \) is a multiple of \( \omega_i^\vee \), then \( t_{-\lambda} \in W_{af}^\circ \) covers only \( s_t t_{-\lambda} \) in the
Bruhat order of \( W_{af}^\circ \). It follows that \( H_{G}(\ell_{-\lambda} + 2) \) is one-dimensional, spanned
by \( \xi_{s_t t_{-\lambda}} \). Similarly the weight space \( V_\lambda(\lambda - \alpha_i^\vee) \) is one-dimensional. If we let
\([MV_{\lambda,v}] \) be the unique MV-cycle with \( v \) of weight \( \nu = \lambda - \alpha_i^\vee \), then this gives a
cycle in homology of degree \( 2(\ell(\lambda) + \ell(\nu)) = 4 \ell(\lambda) - 2 = 2\ell(t_{-\lambda}) - 2 \). So we
have that the homology class \([MV_{\lambda,v}] \) is a positive integer multiple of the Schubert
class \( \xi_{s_t t_{-\lambda}} \). Proposition 4.1 allows one to write \([MV_{\lambda,v}] \) as a matrix coefficient on
\( X \) and compare it with Kostant’s formula for \( q_0 \sigma_{s_t} \). Finally we see in this way that
\( q_0 \sigma_{s_t} \) is a positive integral multiple of \( \xi_{s_t t_{-\lambda}} \) as function on \( X_B \).

Now we can compose this isomorphism \( H^*(G/B)[q_1^{-1}, \ldots, q_n^{-1}] \cong O(X_B) \cong H_s(Gr(G))[[\xi_{s_t}^{-1}]] \) which we have just seen takes \( \sigma_{s_t} \) to a positive integral multiple of
\( \xi_{s_t t_{-\lambda}} \), with the isomorphism \( H_s(Gr(G))[[\xi_{s_t}^{-1}]] \to qH^*(G/B)[q_1^{-1}, \ldots, q_n^{-1}] \) defined
by (6.4) going the other way. This way we get a map \( qH^*(G/B)[q_1^{-1}, \ldots, q_n^{-1}] \to
qH^*(G/B)[q_1^{-1}, \ldots, q_n^{-1}] \) which takes every \( q_i \) to \( q_0 \), but \( \sigma_{s_t} \) to a positive integral
multiple of \( \sigma_{s_t} \). However the images of the \( \sigma_{s_t} \) still need to obey the quadratic
relation in the quantum cohomology ring, which arises from the Hamiltonian of
the Toda lattice [18]. This quadratic relation identifies a quadratic form in the
\( \sigma_{s_t} \)’s with a linear form in the \( q_i \)’s. The quadratic form arises from the invariant
symmetric bilinear form on \( \mathfrak{h}^* \), with the fundamental weights \( \omega_i \) identified with \( \sigma_{s_t} \).
Since this form is non-degenerate, the \( \sigma_{s_t} \)’s cannot be rescaled by positive integer multiples and this relation still hold, unless all of the integer factors are 1, which
means that \( \sigma_{s_t} \) must go to \( \sigma_{s_t} \).

Since \( qH^*(G/B)[q_1^{-1}, \ldots, q_n^{-1}] \) is generated by the \( \sigma_{s_t} \) as ring over \( \mathbb{C}[q_1^{\pm 1}, \ldots, q_n^{\pm 1}] \)
the map \( qH^*(G/B)[q_1^{-1}, \ldots, q_n^{-1}] \to qH^*(G/B)[q_1^{-1}, \ldots, q_n^{-1}] \) considered above is
the identity. Therefore (6.4) is the inverse to the map \( qH^*(G/B)[q_1^{-1}, \ldots, q_n^{-1}] \cong
O(X_B) \cong H_s(Gr(G))[[\xi_{s_t}^{-1}]] \), and we are done.

7. Main results

In the rest of the paper we will be working with the \( \mathbb{R} \)-structures on all our
main objects. Since \( X, Y, H_s(Gr(G)), qH^*(G/P) \) are in fact all defined over \( \mathbb{Z} \) there
is no problem with this. All our notations for positivity and nonnegativity refer to
\( \mathbb{R} \)-points. We now define

**(AP)** The subset

\[ X_{af}^{\geq \circ} = \{ x \in X_{af} \mid \xi_w(x) > 0 \text{ for all } w \in W_{af}^\circ \} \]

of affine Schubert positive elements.

**(MVP)** The subset

\[ X_{MV}^{>0} = \{ x \in X_{af} \mid [MV_{\lambda,v}](x) > 0 \text{ for all MV-cycles} \} \]

of MV-positive elements.

**(TP)** The totally positive subset defined by Lusztig’s theory,

\[ X_{>\circ} := X_{af} \cap U_u^{>\circ} \]

**(QP)** The subset

\[ X_{QSchubert}^{>0} := \{ x \in (X_B)_{af} \mid \sigma_w^u(x) > 0 \text{ all } w \in W \} \]

of quantum Schubert positive elements defined in terms of the quantum
Schubert basis and Peterson’s isomorphism \( qH^*(G/B)[q_1^{-1}, \ldots, q_n^{-1}] \cong O(X_B) \).
We also define the totally nonnegative part \( X_{\geq 0} = X_\mathbb{R} \cap U_{\geq 0} \) of \( X \), and the affine Schubert nonnegative part \( X_{\geq 0}^{af} \) of \( X \) as the set of points \( x \in X_\mathbb{R} \) such that \( \xi_w(x) \geq 0 \) for every affine Schubert class \( \xi_w \).

We note that by (6.3) affine Schubert positivity is equivalent to quantum Schubert positivity with additional positivity of the quantum parameters. Therefore we have an immediate inclusion \( X_{\geq 0}^{af} \subset X_{>0}^{qSchubert} \). We can now state our first main theorem.

**Theorem 7.1.** The first three notions of positivity in \( X \) agree: we have \( X_{>0} = X_{>0}^{af} = X_{>0}^{MV} \). For the fourth notion we have the inclusion \( X_{>0} \subset X_{>0}^{qSchubert} \).

By this Theorem the first three notions of positivity are equivalent, and the fourth is at worst weaker. We in fact conjecture all four of the notions to be equivalent.

**Conjecture 7.2.** We have \( X_{>0} = X_{>0}^{qSchubert} \).

Conjecture 7.2 was shown to hold for type \( A \) in [36]. We will verify it in Appendix A for type \( C \).

Our second main result is about a description of the totally nonnegative part of \( X \) and its stratification. By the isomorphism
\[
\mathbb{C}[Y^*] \cong qH^*(G/P)[(q_1^P)^{-1}, \ldots, (q_k^P)^{-1}]
\]
from Theorem 6.3 combined with \( X_P \cong Y_P \) we have a morphism
\[
\pi^P = (q_1^P, \ldots, q_k^P) : X_P \to (\mathbb{C}^*)^k.
\]
Let \( X_{P,>0} := X_P \cap X_{\geq 0} \). In particular \( X_{B,>0} = X_{>0} \).

**Theorem 7.3.**

1. \( \pi^P \) restricts to a bijection
\[
\pi^P_{>0} : X_{P,>0} \to \mathbb{R}_{>0}^k.
\]
2. \( X_{P,>0} \) lies in the smooth locus of \( X_P \), and the map \( \pi^P \) is étale on \( X_{P,>0} \).
3. The maps \( \pi^P_{>0} \) glue to give a homeomorphism
\[
\Delta_{>0} : X_{>0} \to \mathbb{R}_{>0}^n.
\]

8. **ONE DIRECTION OF THEOREM 7.1**

The main goal of this section is to show that
\[
X_{\geq 0}^{af} \subseteq X_{\geq 0}^{MV} \subseteq X_{>0}.
\]

**Lemma 8.1.** If \( x \in X \) is affine Schubert positive, then it is MV-positive.

**Proof.** The main result of Kumar and Nori [24], applied to \( Gr_G \), shows that every effective cycle in \( Gr_G \) is homologous to a positive sum of Schubert cycles. It follows that the fundamental class \( [MV_{\lambda,v}] \) of an MV-cycle is a positive linear combination of the Schubert classes \( \xi_w \).

**Lemma 8.2.** Suppose \( X_{\geq 0}^{MV} \cap X_{>0} \neq \emptyset \). Then \( X_{>0}^{MV} \subseteq X_{>0} \).
Proof. Suppose $V_\lambda$ is an irreducible representation of $G^\vee$ with highest weight $\lambda$ and $\mu$ is a weight of $V_\lambda$ with one-dimensional weight space.

We work with the geometric Satake equivalence with $\mathbb{R}$-coefficients. Let $[MV_{\lambda,\mu}]$ be the $MV$-cycle representing a weight vector $v$ with weight $\mu$ in $V_{\lambda,\mathbb{R}}$ under the isomorphism (4.2). Then for $x \in X_{\mathbb{R}}$, we have by Proposition 4.1, $[MV_{\lambda,\mu}](x) = \langle x, [MV_{\lambda,\mu}] \rangle = \langle x \cdot v, v_\lambda^- \rangle = \langle v, x^T \cdot v_\lambda^- \rangle$. Note that we are really thinking of $V_{\lambda,\mathbb{R}}$ as a lowest weight representation by fixing the lowest weight vector $v_\lambda$ (of weight $w_0 \lambda$).

Now suppose that there is a vector $v'$ in the weight space $V_{\lambda,\mathbb{R}}(\mu)$ satisfying $\langle v', y \cdot v_\lambda^- \rangle > 0$ for all $y \in U_{\mathbb{R}}^+$. Since the weight space $V_{\lambda,\mathbb{R}}(\mu)$ is one-dimensional it follows that the $MV$-basis element $v = c_{\lambda,\mu} v'$ for a scalar $c_{\lambda,\mu}$. Choose $x_0 \in X_{MV}^{\mathbb{R}} \cap X_0$. Such an $x_0$ exists by our assumption. Then we see that the scalar is positive,

$$c_{\lambda,\mu} = \frac{\langle x_0 \cdot v, v_\lambda^- \rangle}{\langle v', x_0^T \cdot v_\lambda^- \rangle} > 0.$$

(Here, if $x_0 = y_{i_1}(a_1) y_{i_2}(a_2) \cdots y_{i_t}(a_t) \in U_{\mathbb{R}}^-$, then $x_0^T = x_{i_t}(a_t) \cdots x_{i_2}(a_2) x_{i_1}(a_1) \in U_{\mathbb{R}}^+$.)

Now suppose $x \in X_{MV}^{\mathbb{R}}$ is an arbitrary element. Then

$$\langle v', x^T \cdot v_\lambda^- \rangle = \frac{1}{c_{\lambda,\mu}} \langle v, x^T \cdot v_\lambda^- \rangle = \frac{1}{c_{\lambda,\mu}} [MV_{\lambda,\mu}](x) > 0.$$

By Proposition 3.3 (applied with 'positive Borel' $B^+$ taken to be $B^{'G}$), this implies that $x^T$ is totally positive. Clearly then $x$ is totally positive.

Lemma 8.3. The principal nilpotent $f' = \sum f_i'''$ goes to a positive multiple of the affine Schubert class $\xi^{s_{\lambda,t}} \in H^2(Gr_G)$ under the isomorphism $U(\mathfrak{g}_F^{'G}) \cong H^*(Gr_G)$.\[\Box\]

Proof. Since $H^2(Gr_G)$ is 1-dimensional we know that $f' = c \xi^{s_{\lambda,t}}$ under the identification $U(\mathfrak{g}_F^{'G}) \cong H^*(Gr_G)$. We want to show that $c$ is positive.

Consider the exponential $\exp(f') = \exp(c \xi^{s_{\lambda,t}})$ as an element of the completion $H^*(Gr_G)$, and choose $\lambda$ such that $s_{\lambda,t} \in W_{\mathbb{R}}$. If we evaluate the (localized) homology class $\xi_{s_{\lambda,t}} \xi_{t_{\lambda}}^{-1}$ on this element we obtain

$$\xi_{s_{\lambda,t}} \xi_{t_{\lambda}}^{-1}(\exp(f')) = \xi_{s_{\lambda,t}} \xi_{t_{\lambda}}^{-1}(\exp(c \xi^{s_{\lambda,t}})) = \xi_{s_{\lambda,t}} \xi_{t_{\lambda}}^{-1}(1 + c \xi^{s_{\lambda,t}} + \frac{c^2}{2!}(a_2) + \frac{c^3}{3!}(a_3) + \cdots) = \frac{k!}{(k-1)!} c \xi_{s_{\lambda,t}}(a_{k-1}) \xi_{t_{\lambda}}(a_k)^{-1} = \frac{k}{c} \xi_{s_{\lambda,t}}(a_{k-1}) \xi_{t_{\lambda}}(a_k)^{-1},$$

where $\ell(t_{\lambda}) = k = \ell(s_{\lambda,t}) + 1$ and the $a_i$ in $H^2(Gr_G)$ are positive linear combinations of Schubert classes, since all cup product Schubert structure constants of $H^*(Gr_G)$ are positive [24]. Therefore $c$ is positive if and only if $\xi_{s_{\lambda,t}} \xi_{t_{\lambda}}^{-1}(\exp(f'))$ is positive.

We now compute $\xi_{s_{\lambda,t}} \xi_{t_{\lambda}}^{-1}(\exp(f'))$ in a different way. Under Peterson’s isomorphism (6.3)

$$\xi_{s_{\lambda,t}} \xi_{t_{\lambda}}^{-1} \mapsto \sigma_{s_{\lambda,t}}$$

(8.1)
Consider the element of $X_{>0}$, the totally positive part of $X_B$, given by $\exp(f^\vee)$. Using (8.1) and identifying both $H_*(\text{Gr}_G)$ and $qH^*(G/B)[q_1^{-1}, \ldots, q_n^{-1}]$ with $\mathbb{C}[X_B]$ as in (6.3), we can evaluate
\begin{equation}
\xi_{s_i t_s}^{-1}(\exp(f^\vee)) = \sigma_{s_i}(\exp(f^\vee)).
\end{equation}

The right hand side here is a quotient of two ‘chamber minors’ of $\exp(f^\vee)$ by Kostant’s formula [21, Proposition 33]. Therefore the total positivity of $\exp(f^\vee)$ implies
\begin{equation}
\xi_{s_i t_s}^{-1}(\exp(f^\vee)) > 0.
\end{equation}

**Lemma 8.4.** The element $x = \exp(f^\vee)$ lies in $X_{>0}^\text{af}$.

**Proof.** A Schubert class $\xi_w$ in $H_*(\text{Gr}_G)$ can be evaluated against $\exp(f^\vee)$ by viewing $f^\vee$ as element of $H^2(\text{Gr}_G)$, expanding $\exp(f^\vee)$ as a power series and pairing $\xi_w$ with each summand. But Lemma 8.3 implies that $\exp(f^\vee)$ expands as a positive linear combination of Schubert classes. This implies that $\xi_w(\exp(f^\vee)) > 0$ for all $w \in W^-_{\text{af}}$.

**Lemma 8.5.** We have $X_{>0}^{\text{MV}} \subseteq X_{>0}$ and $X_{\geq 0}^{\text{MV}} \subseteq X_{>0}$.

**Proof.** In Lemma 8.4 we found a totally positive point $x \in X_{>0}$, namely $x = \exp(f^\vee)$, which is also affine Schubert positive. Since affine Schubert positive implies MV-positive, by Lemma 8.1, this means that $x \in X_{>0}^{\text{MV}} \cap X_{>0}$. Now Lemma 8.2 implies that $X_{>0}^{\text{MV}} \subseteq X_{>0}$. The second inclusion is an immediate consequence.

**Corollary 8.6.** We have $X_{>0}^\text{af} \subseteq X_{>0}^{\text{MV}} \subseteq X_{>0}$ and $X_{\geq 0}^\text{af} \subseteq X_{\geq 0}^{\text{MV}} \subseteq X_{>0}$.

### 9. Parametrizing the affine Schubert-positive part of $X_P$

Let $X_{P,>0}^\text{af}$ denote the set of points $x \in (X_P)_\mathbb{R}$ such that $\xi_w(x) \geq 0$ for every affine Schubert class $\xi_w$, so
\[X_{P,>0}^\text{af} := X_{\geq 0}^\text{af} \cap X_P.
\]

Note that while some of the functions $\xi_w$ will vanish identically on $X_P$, the ones that don’t will be strictly positive. Hence the notation of $X_{P,>0}^\text{af}$. The goal of this section is to provide $X_{P,>0}^\text{af}$ with a natural bijection to $\mathbb{R}_+^k$.

Recall the map $\pi^P : X_P \to (\mathbb{C}^*)^k$ from (7.1) defined by $\pi^P(x) = (q^P_i(x))_{i=1}^k$. We begin by observing that $\pi^P$ when restricted to $X_{P,>0}^\text{af}$ takes values in $\mathbb{R}_+^k$. We saw already that $q^P_i(x) \neq 0$ for $x \in X_P$, by identification of $X_P$ with $Y^*_P$. Expressing the quantum parameters $q^P_i$ in terms of affine Schubert classes $\xi_{\lambda_i}$ using Theorem 6.4(2), it follows that $x \in X_{P,>0}^\text{af}$ has $q^P_i(x) > 0$ for all $i \in I^P$. We also have strict positivity for the quantum Schubert classes, as in the next Lemma.

**Lemma 9.1.** Suppose $x \in X_{P,>0}^\text{af}$. Then $\sigma^P_w(x) > 0$ for all $w \in W^P$.

**Proof.** It follows from Theorem 6.4(2) and the definitions that $\sigma^P_w(x) \geq 0$. Suppose $\sigma^P_w(x) = 0$. Let $r_\emptyset$ denote the reflection in the longest root, and $\pi_P(r_\emptyset) \in W^P$ be the corresponding minimal length parabolic coset representative. Proposition 11.2 of [25] states that
\[\sigma^P_{\pi_P(r_\emptyset)} \sigma^P_w = q_{NP}(\theta^\vee - w^{-1} \theta^\vee) \sigma^P_{\pi_P(r_\emptyset w)} + q_{NP}(\theta^\vee) \sum_{s_i w < w} a^\vee_i \sigma^P_{s_i w}.
\]
We refer the reader to Appendix A and [25] for the notation used here. Applying this repeatedly, we see that for large $\ell$, the product $(\sigma^P_{\pi^P(r_{\ell})})^\ell \sigma^P_{w}$ is a (positive) combination of quantum Schubert classes which includes a monomial in the $q^P_i$. This contradicts $q^P_i(x) > 0$ for each $i$. □

Remark 9.2. We note that the Lemma 9.1 together with the positivity of the quantum parameters implies that we have $X^af_{B_+,0} = X^af_{>0}$.

The remainder of this section will be devoted to the proof of the following proposition.

**Proposition 9.3.** The map $\pi^P_{>0} : X^af_{P,>0} \to \mathbb{R}^k_{>0}$ is bijective.

We follow the proof in type $A$ given in [36], shortening somewhat the proof of our Lemma 9.5 below (Lemma 9.3 in [36]), by using a result of Fulton and Woodward [11]: the quantum product of Schubert classes is always nonzero.

Fix a point $Q \in (\mathbb{R}_{>0})^k$ and consider its fiber under $\pi = \pi^P$. Let us define

$$R_Q := qH^*(G/P)/(q^P_1 - Q_1, \ldots, q^P_k - Q_k).$$

This is the (possibly non-reduced) coordinate ring of $\pi^{-1}(Q)$. Note that $R_Q$ is a $|W^P|$-dimensional algebra with basis given by the (image of the) Schubert basis. We will use the same notation $\sigma^P_w$ for the image of a Schubert basis element from $qH^*(G/P)$ in the quotient $R_Q$. The proof of the following result from [36] holds in our situation verbatim.

**Lemma 9.4 ([36, Lemma 9.2]).** Suppose $\mu \in R_Q$ is a nonzero simultaneous eigenvector for all linear operators $R_Q \to R_Q$ which are defined by multiplication by elements in $R_Q$. Then there exists a point $p \in \pi^{-1}(Q)$ such that (up to a scalar factor)

$$\mu = \sum_{w \in W^P} \sigma^P_{w}(p) \sigma^P_{D(w)}.$$

□

Set

$$\sigma := \sum_{w \in W^P} \sigma^P_w \in R_Q.$$

Suppose the multiplication operator on $R_Q$ defined by multiplication by $\sigma$ is given by the matrix $M_\sigma = (m_{v,w})_{v,w \in W^P}$ with respect to the Schubert basis. That is,

$$\sigma \cdot \sigma^P_v = \sum_{w \in W^P} m_{v,w} \sigma^P_w.$$

Then since $Q \in \mathbb{R}^k_{>0}$ and by positivity of the structure constants it follows that $M_\sigma$ is a nonnegative matrix.

**Lemma 9.5 ([36, Lemma 9.3]).** There is no subset $V$ of $W^P$ such that the linear span of the set $\{\sigma^P_w \mid w \in V\}$ is invariant under the action of $M_\sigma$. In other words, $M_\sigma$ is an indecomposable matrix.

**Proof.** Suppose indirectly that the matrix $M_\sigma$ is reducible. Then there exists a nonempty, proper subset $V \subset W^P$ such that the span of $\{\sigma_v \mid v \in V\}$ in $R_Q$ is invariant under $M_\sigma$. We will derive a contradiction to this statement.
First let us show that the smallest element, 1, in \( WP \) lies in \( V \). Suppose not. Since \( V \neq \emptyset \) we have a \( v \neq 1 \) in \( V \). Since \( 1 \notin V \), the coefficient of \( \sigma_1 \) in \( \sigma_w \cdot \sigma_v \) must be zero for all \( w \in WP \), or equivalently

\[
(9.1) \quad \langle \sigma_w \cdot \sigma_v \cdot \sigma_{w_0}^P \rangle_Q = 0
\]

for all \( w \in WP \). Here by the bracket \( \langle \quad \rangle_Q \) we mean \( \langle \quad \rangle_Q \) evaluated at \( Q \). But this relation (9.1) implies \( \langle \sigma_w \cdot \sigma_v \cdot \sigma_{w_0}^P \rangle_Q = 0 \), since the latter is a nonnegative polynomial in the \( q_i \)'s which evaluated at \( Q \in \mathbb{R}_{\geq 0}^k \) equals 0. Therefore it follows that \( \sigma_v \cdot \sigma_{w_0}^P = 0 \) in \( qH^*(G/P) \), by quantum Poincaré duality. This leads to a contradiction, since by work of W. Fulton and C. Woodward [11] no two Schubert classes in \( qH^*(G/P) \) ever multiply to zero.

So \( V \) must contain 1. Since \( V \) is a proper subset of \( WP \) we can find some \( w \notin V \). In particular, \( w \neq 1 \). It is a straightforward exercise that given \( 1 \neq w \in WP \) there exists \( \alpha \in \Delta^P_\sigma \) and \( v \in WP \) such that

\[
w = vr_\alpha, \quad \text{and} \quad \ell(w) = \ell(v) + 1.
\]

Now \( \alpha \in \Delta^P_\sigma \) means there exists \( i \in IP \) such that \( \langle \alpha, \omega_i^\vee \rangle \neq 0 \). And hence by the (classical) Chevalley Formula we have that \( \sigma_s_i \cdot \sigma_v \) has \( \sigma_w \) as a summand. But if \( w \notin V \) this implies that also \( v \notin V \), since \( \sigma \cdot \sigma_v \) would have summand \( \sigma_s_i \cdot \sigma_v \) which has summand \( \sigma_w \). Note that there are no cancellations with other terms by positivity of the structure constants.

By this process we can find ever smaller elements of \( WP \) which do not lie in \( V \) until we end up with the identity element, so a contradiction. \( \square \)

Given the indecomposable nonnegative matrix \( M_\sigma \), then by Perron-Frobenius theory (see e.g. [29] Section 1.4) we know the following.

The matrix \( M_\sigma \) has a positive eigenvector \( \mu \) which is unique up to scalar (positive meaning it has positive coefficients with respect to the standard basis).

Its eigenvalue, called the Perron-Frobenius eigenvalue, is positive, has maximal absolute value among all eigenvalues of \( M_\sigma \), and has algebraic multiplicity 1.

The eigenvector \( \mu \) is unique even in the stronger sense that any nonnegative eigenvector of \( M_\sigma \) is a multiple of \( \mu \).

Suppose \( \mu \) is this eigenvector chosen normalized such that \( \langle \mu \rangle_Q = 1 \). Then since the eigenspace containing \( \mu \) is 1–dimensional, it follows that \( \mu \) is joint eigenvector for all multiplication operators of \( R_Q \). Therefore by Lemma 9.4 there exists a \( p_0 \in \pi^{-1}(Q) \) such that

\[
\mu = \sum_{w \in WP} \sigma_w^P(p_0) \sigma_{PD(w)}^P.
\]

Positivity of \( \mu \) implies that \( \sigma_w^P(p_0) \in \mathbb{R}_{\geq 0} \) for all \( w \in WP \). Of course all of the \( q_i(p_0) = Q_i \) are positive too. Hence \( p_0 \in X_{P,>0}^f \). Also the point \( p_0 \) in the fiber over \( Q \) with the property that all \( \sigma_w^P(p_0) \) are positive is unique. Therefore

\[
(9.2) \quad X_{P,>0}^f \rightarrow \mathbb{R}_{>0}^k
\]

is a bijection and Proposition 9.3 is proved.
10. Proof of Theorem 7.3(2)

We establish Theorem 7.3(2) for $X_{P,>0}^a$ instead of $X_{P,>0}$. In Proposition 11.3, we will establish the equality $X_{P,>0}^a = X_{P,>0}$.

Since $qH^*(G/P)$ is free over $\mathbb{C}[q_1^e, \ldots, q_k^e]$, it follows that $\pi^P$ is flat. Let $Q = \pi^P(p_0)$. Let $R = qH^*(G/P)$ and $I \subset R$ the ideal $(q_1 - Q_1, \ldots, q_k - Q_k).$

The Artinian ring $R_Q = R/I$ is isomorphic to the sum of local rings $R_Q \cong \bigoplus_{x \in (\pi^P)^{-1}(Q)} R_x/I R_x$. And for $x = p_0$ the local ring $R_{p_0}/I R_{p_0}$ corresponds to $R_Q$ to the Perron–Frobenius eigenspace of the multiplication operator $M_x$ from the above proof. Since this is a one-dimensional eigenspace (with algebraic multiplicity one) we have that $\dim(R_{p_0}/I R_{p_0}) = 1$. It follows that the map $\pi^P$ is unramified at the point $p_0$. Thus, for example by [17, Ex.III.10.3], $\pi^P$ is étale at $p_0$. Since $(\mathbb{C}^*)^k$ is smooth, it follows that $X_P$ is smooth at $p_0$.

11. Proofs of Theorem 7.1 and Theorem 7.3(1)

Lemma 11.1. $X_{\geq 0}$ and $X_{\geq 0}^a$ are closed subsemigroups of $X$.

Proof. For $X_{\geq 0}$ this follows from the fact that $(U^\vee)_{\geq 0}$ is a closed subsemigroup of $U^\vee$, and $X \subset U^\vee$ is a closed subgroup. For $X_{\geq 0}^a$ being a closed subset follows from the definition. For the semigroup structure, suppose $x,y \in X_{\geq 0}^a$. Then for any affine Schubert class $\xi_w$, we have

$$\xi_w(xy) = \Delta(\xi_w)(x \otimes y) = \sum_{v,u} c_{w,v,u}^w \xi_v(x) \otimes \xi_u(y) \geq 0$$

where $\Delta$ denotes the coproduct of $H_*(Gr_G)$, and $c_{w,v,u}^w \geq 0$ are nonnegative integers [24]. Thus $xy \in X_{\geq 0}^a$. □

The first statement of Theorem 7.1 follows from Corollary 8.6 and the following proposition.

Proposition 11.2. The totally positive part and the affine Schubert positive part of $X$ agree,

$$X_{\geq 0}^a = X_{\geq 0}.$$

Proof. Our proof is identical to the proof of Proposition 12.2 from [36].

By [21, Section 5] or combining Theorem 6.3 with [13, Proposition 1.9], we see that each $q_i$ is a ratio of ‘chamber minors’ and so $\pi^B$ takes positive values on $X_{>0}$. By Corollary 8.6 we have the following commutative diagram

$$
\begin{array}{ccc}
X_{\geq 0}^a & \hookrightarrow & X_{\geq 0} \\
\cap & \downarrow & \downarrow \\
\mathbb{R}^n_{\geq 0} & \leftrightarrow & \mathbb{R}^n_{\geq 0}
\end{array}
$$

where the top row is clearly an open inclusion and the maps going down are restrictions of $\pi^B$. By (9.2) and Section 10, the left hand map to $\mathbb{R}^n_{\geq 0}$ is a homeomorphism. It follows from this and elementary point set topology that $X_{\geq 0}^a$ must be closed inside $X_{\geq 0}$. So it suffices to show that $X_{>0}$ is connected.

For an arbitrary element $u \in X$ and $t \in \mathbb{R}$, let

$$(11.1) \quad u_t := t^{-\rho} ut^\rho,$$
where \( t \mapsto t^\rho \) is the one-parameter subgroup of \( T^\vee \) corresponding to the coroot \( \rho \) (a coroot relative to \( G^\vee \)). Then \( u_0 = e \) and \( u_1 = u \), and if \( u \in X_{>0} \), then also \( u_t \in X_{>0} \) for all positive \( t \).

Let \( u, u' \in X_{>0} \) be two arbitrary points. Consider the paths

\[
\begin{align*}
g : [0, 1] &\to X_{>0}, \quad g(t) = uu'_t, \\
g' : [0, 1] &\to X_{>0}, \quad g'(t) = uu'_t.
\end{align*}
\]

Note that these paths lie entirely in \( X_{>0} \) since \( X_{>0} \) is a semigroup (Lemma 11.1). Since \( g \) and \( g' \) connect \( u \) and \( u' \), respectively, to \( uu' \), it follows that \( u \) and \( u' \) lie in the same connected component of \( X_{>0} \), and we are done. \( \square \)

The second statement of Theorem 7.1 and Theorem 7.3(1) follow from:

**Proposition 11.3.** We have \( \overline{X_{>0}} = X_{\geq 0} \) and \( \overline{X_{>0}} = X_{\geq 0} \). Moreover \( X_{>0} = X_{\geq 0} \) and for each \( P \)

\[
X_{P,>0} = X_{P,\geq 0}.
\]

**Proof.** Since \( X_{\geq 0} \) is closed and contains \( X_{>0} \) we clearly have that \( \overline{X_{>0}} \subset X_{\geq 0} \). Suppose \( x \in X_{>0} \). Then for any \( u \in X_{>0} \), we have \( u_t \in X_{>0} \) for all positive \( t \), where \( u_t \) is defined in (11.1). The curve \( t \mapsto x(t) = xu_t \) starts at \( x(0) = x \) and lies in \( X_{>0} \) for all \( t > 0 \), compare [27]. Therefore \( x \in \overline{X_{>0}} \) as desired and we have proved the first equality, \( X_{\geq 0} = X_{>0} \).

Now \( X_{\geq 0}^\text{af} \) is a closed semigroup in \( X_{>0} \) by a combination of Lemma 11.1 and Corollary 8.6. On the other hand since \( X_{\geq 0}^\text{af} = X_{>0} \) by Proposition 11.2, we have \( X_{\geq 0}^\text{af} = \overline{X_{>0}} = X_{>0} = X_{\geq 0} \). If follows that \( X_{\geq 0} = X_{>0} = X_{\geq 0} \). \( \square \)

12. **Proof of Theorem 7.3(3)**

To define \( \Delta_{\geq 0} \), we set \( \Delta_i = \xi_{t, m_i \omega_i^\vee} \), where \( m_i \) is chosen so that \( m_i \omega_i^\vee \in Q^\vee \). Then \( \Delta_{\geq 0} = (\Delta_1, \ldots, \Delta_n) \).

It follows from the explicit description [25] of \( \pi_P(t, \lambda) \) and \( \eta_P(\lambda) \) of Theorem 6.4 that for each \( i \), some power of \( q_i^\rho \) is equal to \( \xi_\lambda \xi_\mu^{-1} \) on \( X_P \), for certain \( \lambda, \mu \in Q^\vee \). Furthermore, the map

\[
\pi_{\geq 0}^P = (q_1^P, \ldots, q_k^P) : X_{P,>0} \to \mathbb{R}_{>0}^k
\]

is related to the map

\[
\Delta_{\geq 0}^P = (\Delta_{i_1}, \Delta_{i_2}, \ldots, \Delta_{i_k}) : X_{P,>0} \to \mathbb{R}_{>0}^k
\]

by a homeomorphism of \( \mathbb{R}_{>0}^k \), where \( I^P = \{i_1, i_2, \ldots, i_k\} \). But \( X_{\geq 0} = \bigsqcup X_{P,>0} \), so we have that

\[
\Delta_{\geq 0} : X_{\geq 0} \to \mathbb{R}_{\geq 0}^n
\]

is bijective. So \( \Delta_{\geq 0} \) is continuous and bijective. Since \( \Delta \) is finite it follows that it is closed, that is, takes closed sets to closed sets. (This holds true also in the Euclidean topology, since the preimage of a bounded set under a finite map must be bounded, compare [40, Section 5.3]). Since \( X_{\geq 0} \) is closed in \( X \) the restriction \( \Delta_{\geq 0} \) of \( \Delta \) to \( X_{\geq 0} \) is also closed. Therefore \( \Delta_{\geq 0}^{-1} \) is continuous.
13. Proof of Proposition 3.3

It suffices to prove the Proposition for \( G \) of adjoint type. Call a dominant weight \( \lambda \) allowable if it is a character of the maximal torus of adjoint type \( G \).

We note that the tensor product \( V = V_\lambda \otimes V_\mu \) of two irreducible representations inherits a tensor Shapovalov form \( \langle \cdot, \cdot \rangle \) defined by \( \langle v \otimes w, v' \otimes w' \rangle = \langle v, v' \rangle \langle w, w' \rangle \). This is again a positive-definite non-degenerate symmetric form on \( V_\lambda \otimes V_\mu \) satisfying (3.1). Note that for weight vectors \( v_1, v_2 \in V \), we have \( \langle v_1, v_2 \rangle = 0 \) unless \( v_1 \) and \( v_2 \) have the same weight. It follows that if \( V_\nu, V_\rho \subset V \) are irreducible subrepresentations, and \( \nu \neq \rho \) then \( \langle v, v' \rangle = 0 \) for \( v \in V_\nu \) and \( v' \in V_\rho \). Thus if the highest-weight representation \( V_\nu \) occurs in \( V \) with multiplicity one, the restriction of \( \langle \cdot, \cdot \rangle \) from \( V \) to \( V_\nu \) must be a positive-definite non-degenerate symmetric bilinear form satisfying (3.1), and thus must be a multiple of the Shapovalov form. By scaling the inclusion \( V_\nu \subset V \), we shall always assume that the restricted form is the Shapovalov form. The above comments extend to the case of \( n \)-fold tensor products.

We shall need the following result.

**Lemma 13.1.** Let \( \omega \) be a fundamental weight, \( \alpha_i \) be the corresponding simple root, and let \( \eta = 2\omega - \alpha_i \).

1. Define an equivalence relation on \( W \cdot \omega \) generated by \( \lambda \sim \mu \) if \( \lambda + \mu \in W \cdot \eta \). Then this equivalence relation has a single equivalence class.
2. \( \eta \) appears as a weight in \( V_{2\omega} \) with multiplicity 1. The weight \( \eta \) appears as a weight in \( V_\omega \otimes V_\omega \) with multiplicity 2.
3. \( V_{2\omega} \) occurs as an irreducible summand of \( V_\omega \otimes V_\omega \) with multiplicity 1.

**Proof.** We prove (1). It is clear from the definition that if \( \lambda \sim \mu \) then \( w \cdot \lambda \sim w \cdot \mu \) for any \( w \in W \). Since \( \omega + s_i \cdot \omega = \eta \), we have \( \omega \sim s_i \omega \). Let \( W_P \subset W \) be the parabolic subgroup that is the stabilizer of \( \omega \). Then clearly \( \omega \sim v \cdot \omega \) for any \( v \in W_P \). Since \( W \) is generated by \( s_i \) and \( W_P \), it follows that \( \omega \sim v \cdot \omega \) for any \( v \in W_P \). (1) follows.

The first statement of (2) follows from the fact that \( 2\omega - \eta = \alpha_i \) is a simple root. The second statement of (2) follows by inspection of the weights of \( V_\omega \). (3) is straightforward. \( \square \)

13.1. Type \( A_n \). We shall establish the criterion used in Proposition 3.2. First suppose \( n \) is even. Let \( V_{\omega_i, \mathbb{R}} \) be a fundamental representation, and let \( v_{\omega_i}^+ \in V_{\omega_i, \mathbb{R}} \) be the highest weight vector, and \( v = w \cdot v_{\omega_i}^+ \) an extremal weight vector. The weight space with weight \( w \cdot (n+1)\omega_i \) is extremal (and one-dimensional) in \( V_{(n+1)\omega_i, \mathbb{R}} \) and \( V_{(n+1)\omega_i, \mathbb{R}} \) is an irreducible representation for \( \text{PSL}_{n+1} \). Thus for \( y \) as in Proposition 3.2,

\[
\langle v, y \cdot v_{\omega_i}^+ \rangle^{n+1} = \langle v^\otimes_{(n+1)}, y \cdot (v_{\omega_i}^+) \otimes (n+1) \rangle > 0.
\]

Since \( n \) is even, this implies that \( \langle v, y \cdot v_{\omega_i}^+ \rangle > 0 \).

For odd \( n \), let us fix \( w \in W \), and consider the set of signs \( a_i = \text{sign}(\langle w \cdot v_{\omega_i}, y \cdot v_{\omega_i} \rangle) \). We want to prove that the \( a_i \) are all +1. Note that a sum of (not necessarily distinct) fundamental weights, \( \omega_i + \cdots + \omega_{i_k} \), is allowable precisely if it is trivial on the center of \( S_n \), that is if \( i_1 + \cdots + i_k \) is divisible by \( n+1 \). Let \( (i_1, i_2, \ldots, i_k) \) be such a sequence of indices, for which \( \omega_i + \cdots + \omega_{i_k} \) is allowable. Then the weight \( w(\omega_{i_1} + \cdots + \omega_{i_k}) \) is an extremal weight of the representation \( V_{\omega_{i_1} + \cdots + \omega_{i_k}, \mathbb{R}} \).
of $PSL_{n+1}$, and we have 
\[ \langle \hat{w} \cdot v_{w_1}^+, y \cdot v_{w_1}^+ \rangle \langle \hat{w} \cdot v_{w_2}^+, y \cdot v_{w_2}^+ \rangle \cdots \langle \hat{w} \cdot v_{w_k}^+, y \cdot v_{w_k}^+ \rangle = \langle \hat{w} \cdot (v_{w_1}^+ \otimes \cdots v_{w_k}^+), y \cdot (v_{w_1}^+ \otimes \cdots v_{w_k}^+) \rangle > 0. \]

Therefore $a_1 \ldots a_k = +1$ if $i_1 + \ldots + i_k = n + 1$. In particular $a_i a_{i+1}^{n+1-i} = +1$, implying that $a_i = +1$ for even $i$, and $a_i = -1$ for odd $i$.

We now show that $a_1 = +1$. Let $V = V_{\omega_1, \mathbb{R}} = \mathbb{R}^{n+1}$ with standard basis \{ $v_1, \ldots, v_{n+1}$ \}, and let $Z = V \otimes (n+1)$. If we take $v_{w_1}^+ = v_1$ then the Shapovalov form on $V$ is the standard symmetric bilinear form given by $\langle v_1, v_j \rangle = \delta_{i,j}$. Let us consider $U = V_{(n+1)\omega_1, \mathbb{R}} = \text{Sym}^{n+1}(V)$, which occurs with multiplicity 1 in $Z$ and has standard basis \{ $v_{i_1} \ldots v_{i_{n+1}} \mid 1 \leq i_1 \leq i_2 \leq \ldots \leq i_{n+1} \leq n+1 \} \}$ of symmetrized tensors,
\[ v_{i_1} \ldots v_{i_{n+1}} = \frac{1}{(n+1)!} \sum_{\sigma \in S_{n+1}} v_{\sigma(i_1)} \otimes v_{\sigma(i_2)} \otimes \cdots \otimes v_{\sigma(i_{n+1})}. \]

These are clearly orthonormal for the tensor Shapovalov form restricted to $U$, which is the Shapovalov form (\( \cdot, \cdot \)) of $U$. We have $\hat{w} \cdot v_1 = v_k$ for some $k$. Consider the vector $z = v_1^+ v_k \in U$ which has weight $\hat{w} \cdot \omega_1 + n \omega_1$. Clearly $\langle z, x \cdot v_{(n+1)\omega_1}^+ \rangle_U = \langle v_1^+ v_k, x \cdot v_{1}^{n+1} \rangle_U > 0$ for all totally positive $x \in U_{>0}$, and $z$ lies in a 1-dimensional weight space of $U$. Therefore our assumptions imply that
\[ 0 < \langle z, y \cdot v_{(n+1)\omega_1}^+ \rangle_U = \langle v_1^+ v_k, y \cdot v_{1}^{n+1} \rangle_U = \langle v_1, y \cdot v_1 \rangle^n \langle v_k, y \cdot v_1 \rangle = \langle v_k, y \cdot v_1 \rangle. \]

Since $\langle v_k, y \cdot v_1 \rangle_U = \langle \hat{w} \cdot v_{w_1}^+, y \cdot v_{w_1}^+ \rangle_U$ this says precisely that $a_1 = +1$.

13.2. Type $B_n$. The approach we use for the other Dynkin types can also be applied in this case, but we shall proceed using a different approach. The adjoint group of type $B_n$ is $SO_{2n+1}(\mathbb{C})$. We realize $SO_{2n+1}$ as subgroup of $SL_{2n+1}$ following Berenstein and Zelevinsky in [2] by setting
\[ SO_{2n+1}(\mathbb{C}) = \{ A \in SL_{2n+1}(\mathbb{C}) \mid AJA^t = J \}, \]
for the symmetric bilinear form
\[ J = \begin{pmatrix} & & & 1 \\ & -1 & & \\ & & -1 & \\ 1 & & & -1 \end{pmatrix}, \]
where the signs along the antidiagonal are alternating. Let $\hat{e}_1, \hat{f}_1$ be the usual Chevalley generators of $sl_{2n+1}$. Then we can take $e_i = \hat{e}_i + \hat{e}_{2n+1-i}$ and $f_i = \hat{f}_i + \hat{f}_{2n+1-1}$ to be Chevalley generators of $SO_{2n+1}(\mathbb{C})$, and we have a corresponding pinning. Let $\hat{T}$ denote the maximal torus of diagonal matrices in $SL_{2n+1}(\mathbb{C})$ with character group $X^*(\hat{T}) = \mathbb{Z}(\hat{e}_1, \ldots, \hat{e}_{2n+1})/(\sum \hat{e}_i)$, where $\hat{e}_i(t)$ is the $i$-th diagonal
entry of \( t \). The maximal torus \( T \) of \( SO_{2n+1}(\mathbb{C}) \) in this embedding looks like

\[
T = \left\{ t = \begin{pmatrix} t_1 & \cdots & t_n \\ \vdots & & \ddots & \vdots \\ t_{n-1} & \cdots & 1 \\ t_1 & \cdots & t_{n-1} \end{pmatrix} \mid t_i \in \mathbb{C}^* \right\}.
\]

The restriction of characters from \( \tilde{T} \) to \( T \) gives a map \( \text{Res} \) = \( \text{Res}_{\tilde{T}}^T : X^*(\tilde{T}) \to X^*(T) \), whose kernel is precisely generated by the characters \( \tilde{\varepsilon}_i + \tilde{\varepsilon}_{2n-i+2} \) for \( 1 \leq i \leq n \) and \( \tilde{\varepsilon}_{n+1} \).

By work of Berenstein and Zelevinsky the above realisation of \( SO_{2n+1}(\mathbb{C}) \) as a subgroup of \( SL_{2n+1}(\mathbb{C}) \) has the desirable property that the standard totally non-negative part of \( SO_{2n+1}(\mathbb{C}) \) is the intersection of \( SO_{2n+1}(\mathbb{C}) \) with the totally non-negative part of \( SL_{2n+1}(\mathbb{C}) \).

To prove Proposition 3.3 in this setting we need to consider an element \( y \in U^-_{\mathbb{R}} \subset SO_{2n+1}(\mathbb{C}) \) satisfying the condition (3.2), and for any such element show that \( y \) is a totally positive element of \( U^- \). By [2, Corollary 7.2] this means we can equivalently show that \( y \) is totally positive in \( \tilde{U}^- \), i.e., as a lower uni-triangular element of \( SL_{2n+1} \). To prove total positivity in \( \tilde{U}^- \) we use the ‘Chamber Ansatz’ of Berenstein, Fomin, and Zelevinsky [1].

In the Weyl group \( \tilde{W} \) of \( SL_{2n+1} \) let \( w = (s_1s_2n)(s_2s_{2n-1}) \ldots (s_n,s_{n+1})s_n \). Then multiplying \( w \) with itself \( n \) times gives a reduced expression for the longest element \( w_0 \) of \( \tilde{W} \). By the BFZ Chamber Ansatz we can associate to this reduced expression a set of ‘chamber minors’ which suffice to check the total positivity of any element of \( \tilde{U}^- \subset SL_{2n+1}(\mathbb{C}) \).

The chamber minors can be worked out graphically using the pseudo-line arrangement for the reduced expression. For \( w \) the pseudo-line arrangement is illustrated in Figure 1. We concatenate \( n \) copies of this pseudo-line arrangement together to get the relevant pseudo-line arrangement for \( w_0 \), which we call our preferred pseudo-line arrangement for \( w_0 \).

Recall that a chamber of a pseudo-line arrangement is either a bounded connected component of the complement, or it is a connected region at the right or left-hand end of the arrangement which is bounded by two adjacent lines and an imagined third, vertical, line connecting up the ends of the two adjacent lines. To every chamber in the arrangement we associate a set \( J \subset \{1, \ldots , 2n+1\} \) called a chamber set, by recording the numbers of the lines running below the chamber.

For example, the chamber in Figure 1 which is bounded by lines \( 1, n+1 \) and \( 2n+1 \) has associated to it the set \( J = \{1, n+2, n+3, \ldots , 2n+1\} \). We always order the elements of a chamber set by size, so let \( j_1 < \ldots < j_k \) be the elements of \( J \). Then one associates a minor to \( J \) by setting

\[
\Delta J(y) := \Delta_j(y^T) = \langle y^T , e_{j_1} \land \ldots \land e_{j_k}, v^+_{\omega_k} \rangle = \langle e_{j_1} \land \ldots \land e_{j_k}, y \cdot v^+_{\omega_k} \rangle,
\]

where \( \Delta J \) is the ‘chamber minor’ as defined in [1]. Here \( k = |J| \) and \( v^+_{\omega_k} = e_1 \land \cdots \land e_k \) is the highest weight vector of the irreducible representation \( V_{\omega_k} = \wedge^k \mathbb{C}^{2n+1} \) of
Figure 1. Pseudo-line arrangement for $w$.

$SL_{2n+1}(\mathbb{C})$. The weight $\tilde{\varepsilon}_J := \tilde{\varepsilon}_{j_1} + \cdots + \tilde{\varepsilon}_{j_k}$ associated to the chamber set $J$, which is the weight of the vector $e_{j_1} \wedge \cdots \wedge e_{j_k}$, is called a chamber weight.

By our assumption, $y$ lies in $SO_{2n+1}(\mathbb{C})$ and we know that matrix coefficients of $y$ of a certain type (3.2) are positive. Indeed, a chamber minor $\tilde{\Delta}(y) = \langle e_{j_1} \wedge \cdots \wedge e_{j_k}, y \cdot v_{w_0}^* \rangle$ is a matrix coefficient of this allowable type precisely if $v = e_{j_1} \wedge \cdots \wedge e_{j_k}$ lies in a 1-dimensional weight space of the restricted representation, $Res_{SO_{2n+1}}^{SL_{2n+1}} V_{\tilde{\omega}_k}$. Whether or not this is the case depends entirely on the chamber weight $\tilde{\varepsilon}_J$, and we make the following definition.

**Definition 13.2.** A weight $\tilde{\varepsilon}$ of $\wedge^k \mathbb{C}^{2n+1}$ is said to satisfy the restriction property if for $\varepsilon = \tilde{\varepsilon}|_{h_{SO_{2n+1}}}$ the $\varepsilon$-weight space in the restricted representation

$$Res_{SO_{2n+1}}^{SL_{2n+1}} \left( \wedge^k \mathbb{C}^{2n+1} \right)$$

is 1-dimensional. Equivalently, this is the case if for any weight $\tilde{\eta}$ of $\wedge^k \mathbb{C}^{2n+1}$ the condition $Res(\tilde{\varepsilon}) = Res(\tilde{\eta})$ implies $\tilde{\varepsilon} = \tilde{\eta}$.

To prove Proposition 3.3, it now remains to check that the restriction property holds for all of the chamber weights associated to our preferred pseudo-line arrangement. This will be done in two steps. First we will introduce a combinatorial condition on chamber sets which we show is equivalent to the restriction property on corresponding chamber weights. Then we will demonstrate that the chamber sets in our preferred arrangement for $w_0$ all satisfy this combinatorial condition.

**Definition 13.3.** Let $J$ be a subset of $\{1, \ldots, 2n + 1\}$. We say that $J$ is good if

- either $|J| \leq n$ and for each $j \in J$ we have $2n - 2 + j \notin J$,
- or $|J| \geq n + 1$ and for each $j \notin J$ we have $2n - 2 + j \in J$.

Note that if $J$ is good then its complement $J^c$ is good and vice versa.

**Lemma 13.4.** A subset $J$ of $\{1, \ldots, 2n + 1\}$ is good if and only if the chamber weight $\tilde{\varepsilon}_J$ has the restriction property.

**Proof.** Suppose $R$ is another subset of $\{1, \ldots, 2n + 1\}$ for which $\tilde{\varepsilon}_R = \tilde{\varepsilon}_{r_1} + \cdots + \tilde{\varepsilon}_{r_k}$ is a weight of $\wedge^k \mathbb{C}^{2n+1}$, and that $\tilde{\varepsilon}_R$ and $\tilde{\varepsilon}_J$ have the same restriction to $h_{SO_{2n+1}}$. Therefore $\tilde{\varepsilon}_J - \tilde{\varepsilon}_R$ lies in the kernel of the restriction map which is spanned by

$$\tilde{\varepsilon}_{n+1}, \quad \tilde{\varepsilon}_i + \tilde{\varepsilon}_{2n+2-i} \quad i = 1, \ldots, n.$$
For parity reasons, it follows that $\tilde{\varepsilon}_{n+1}$ either occurs as a summand in both $\tilde{\varepsilon}_R$ and $\tilde{\varepsilon}_J$, or it occurs in neither. Therefore

\begin{equation}
\tilde{\varepsilon}_J - \tilde{\varepsilon}_R = \sum_{i=1}^{n} c_i (\tilde{\varepsilon}_i + \tilde{\varepsilon}_{2n+2-i})
\end{equation}

for some coefficients $c_i$. Moreover necessarily, $c_i = 1$ if $i \in J \setminus R$, while $c_i = -1$ if $i \in R \setminus J$ and $c_i = 0$ otherwise. Therefore if (13.1) holds, then

$$
\tilde{\varepsilon}_J = \sum_{i,c_i=1} (\tilde{\varepsilon}_i + \tilde{\varepsilon}_{2n+2-i}) + \sum_{j \in J \cap R} \tilde{\varepsilon}_j,
$$

$$
\tilde{\varepsilon}_R = \sum_{i,c_i=-1} (\tilde{\varepsilon}_i + \tilde{\varepsilon}_{2n+2-i}) + \sum_{j \in J \setminus R} \tilde{\varepsilon}_j.
$$

If $J$ is good we will now deduce from these observations that the first sums in $\tilde{\varepsilon}_J$ and $\tilde{\varepsilon}_R$ above are zero and $\tilde{\varepsilon}_J = \tilde{\varepsilon}_R$, proving one direction of the Lemma.

Namely suppose first $|J| \leq n$. Then because $J$ is good, $j \in J$ implies $2n+2-j \notin J$. Therefore the coefficient $c_j$ for $j \in J$ must equal 0, and therefore $j$ must lie in $R$. In other words, we have $J \subset R$. Since $|R| = |J| = k$ we see that $R = J$ and the two weights $\tilde{\varepsilon}_J$ and $\tilde{\varepsilon}_R$ agree.

Similarly, if $J$ is good and $|J| \geq n+1$ then $i \notin J$ implies $2n+2-i \in J$. In this case the analogous argument shows that the complement of $J$ is contained in the complement of $R$, $J^c \subset R^c$. Again $|R| = |J| = k$ implies $R = J$.

It remains to prove that if $J$ is not good, then there is a weight $\tilde{\varepsilon}_R$ as above, for which (13.1) holds and for which $\tilde{\varepsilon}_R \neq \tilde{\varepsilon}_J$.

If $|J| \leq n$ then since $J$ is not good, there is a $i \in J$ for which $2n+2-i \in J$ as well. Let $J' := J \setminus \{i, 2n+2-i\}$. Then

$$
\tilde{\varepsilon}_J = (\tilde{\varepsilon}_i + \tilde{\varepsilon}_{2n+2-i}) + \sum_{j \in J'} \tilde{\varepsilon}_j.
$$

Since $|J' \cup \{i\}| \leq n-1$ and there are $n$ pairs of the type $\{k, 2n+2-k\}$ in $\{1, \ldots, 2n+1\}$, there must be at least one pair $\{i', 2n+2-i'\}$ for which neither element lies in $J' \cup \{i\}$, by the pigeon hole principle. Moreover, the pair $\{i', 2n+2-i'\}$ is in the complement of $J$. It follows that for $R := J' \cup \{i', 2n+2-i'\}$, the weight

$$
\tilde{\varepsilon}_R = (\tilde{\varepsilon}_{i'} + \tilde{\varepsilon}_{2n+2-i'}) + \sum_{j \in J'} \tilde{\varepsilon}_j.
$$

is different from $\tilde{\varepsilon}_J$ but has the same restriction. Therefore $J$ does not have the restriction property.

If the subset has cardinality $\geq n+1$ and is not good, then in fact it arises as the complement $J^c$ of a set $J$ which is not good and of cardinality $|J| \leq n$, thus reducing this case to the previous one. Namely $\tilde{\varepsilon}_J$, and $\tilde{\varepsilon}_{R^c}$, where $R^c$ is the complement of the weight $R$ constructed above, are weights which have the same restriction, but are distinct. Therefore the restriction property does not hold for such sets $J^c$. \qed

**Lemma 13.5.** If $J$ is a chamber set for our preferred reduced expression $w_0 = w^n$, then $J$ is good in the sense of Definition 13.3.

**Proof.** The pseudo-line arrangement is made up of $n$ copies of the one in Figure 1. The $j$-th copy is illustrated in Figure 13.2. Consider the involution on $\{1, \ldots, 2n+1\}$ which sends $i$ to $\tilde{i} := 2n+2-i$. Let $L_j$ denote the set of labels of lines that run partly or entirely below the middle line in the $j$-th diagram, which is shown in
Figure 13.2. Here by the middle line we mean the line labelled $n + 1$. Since only lines $j$ and $2n + 2 - j$ cross the middle line, we have $|L_j| = n + 1$. Moreover by construction, the image $\overline{L_j}$ of $L_j$ under the above involution is always the set $U_j$ labelling all of the lines which run partly or entirely above the middle line. Clearly, the chambers lying below the middle line have chamber sets contained in $L_j$. The only chamber set among these to contain both $j$ and $2n + 2 - j$ is $L_j$ itself. This set is good, since it has cardinality $n + 1$ and every label appears either in $L_j$ or $\overline{L_j}$. All other chamber sets below the $n + 1$-line have cardinality $\leq n$ and contain at most one of every pair $\{k, 2n + 2 - k\}$. Therefore these chamber sets are also good. The remaining chamber sets are the ones lying above the middle line. They all have cardinality $\geq n + 1$. By inspection, they must contain either $j$ or $2n + 2 - j$. And they all contain $L_j \setminus \{j, 2n + 2 - j\}$. Therefore they have non-empty intersection with each pair $\{k, 2n + 2 - k\}$. This implies that these chamber sets are also good. □

Proposition 3.3 in the case of $SO_n(\mathbb{C})$ now follows from these two lemmas. Namely, if $y$ satisfies the conditions of Proposition 3.3, then the minor $\Delta_j(y)$ is known to be positive if $J$ is good (Lemma 13.4). On the other hand, we have found a reduced expression for the longest element of the Weyl group of $SL_{2n+1}$ for which the pseudo-line arrangement has the property that all chamber sets are good (Lemma 13.5). By the BFZ chamber ansatz, if there is a reduced expression of the longest element such that all the chamber minors of $y$ are positive then $y$ is totally positive in $\tilde{U}^-$ (within $SL_{2n+1}$). Therefore $y$ is also totally positive in $U^-$ (within $SO_{2n+1}$), by [2, Corollary 7.2].

13.3. Type $C_n$. The order of the weight lattice module the root lattice (index of connection) is 2. Let us choose a basis $\varepsilon_1, \varepsilon_2, \ldots, \varepsilon_n \in \mathfrak{h}_R^*$ so that the long simple root is $\alpha_1 = 2\varepsilon_1$, and the short simple roots are $\alpha_k = \varepsilon_k - \varepsilon_{k-1}$ for $2 \leq k \leq n$. A weight $\lambda = \sum_{i=1}^n a_i \varepsilon_i$ is allowable if and only if $\sum_{i=1}^n a_i$ is even. Note that $\omega_{n-1} = \varepsilon_{n-1} + \varepsilon_n$ is allowable, while $\omega_n = \varepsilon_n$ is not. Suppose $1 \leq i \leq n - 2$ is chosen so that $\omega_i$ is not allowable. Consider $V_{\omega_i + \omega_n, \mathbb{R}} \subset V_{\omega_i, \mathbb{R}} \otimes V_{\omega_n, \mathbb{R}}$. (Note that since $\omega_n$ is also not allowable and the index of connection is 2, $\omega_i + \omega_n$ is allowable.) Then for any $w \in W$ we have

$$\langle \hat{w} \cdot v^+_\omega, y \cdot v^+_{\omega_n}, v^+_{\omega_n} \rangle = \langle \hat{w} \cdot (v^+_\omega \otimes v^+_{\omega_n}), y \cdot (v^+_\omega \otimes v^+_{\omega_n}) \rangle > 0,$$
by assumption (3.2) on \(y\). It remains to show that \(\langle \hat{w} \cdot v_{\omega_n}, y \cdot v_{\omega_n} \rangle > 0\), since then \(\langle \hat{w} \cdot v_{\omega_n}, y \cdot v_{\omega_n} \rangle > 0\) for all \(w \in W\) and fundamental weights \(\omega_i\), whereby \(y\) has to be totally positive, because of Proposition 3.2.

We now consider \(V = V_{\omega_n, \mathbb{R}}\), which is 2\(n\)-dimensional with weights \(\pm \varepsilon_k\) for \(1 \leq k \leq n\). Then \(2\omega_n - \alpha_n = \omega_{n-1}\), and we can apply Lemma 13.1 with \(\omega = \omega_n\) and \(\eta = \omega_{n-1}\). Note that \(2\omega_n\) is allowable.

We may now proceed as in the proof for \(A_n\) for \(n\) odd. We consider the inclusion \(U = V_{2\omega_n, \mathbb{R}} \subset V \otimes V = Z\) and look at a vector \(z \in U\) with weight \(\nu = \lambda + \mu \in W \cdot \omega_{n-1}\). We first argue that \(z\) can be chosen so that \(\langle z, x \cdot v_{2\omega_n}^+ \rangle > 0\) for all totally positive \(x \in U_{>0}\). In [2, Corollary 7.2], Berenstein and Zelevinsky show that there is an inclusion \(S_{\mathfrak{sp}_{2n}}(\mathbb{C}) \rightarrow SL_{2n}(\mathbb{C})\) such that the image of the totally positive part \(U^+_{>0}\) of the unipotent of \(S_{\mathfrak{sp}_{2n}}\) lies in the totally nonnegative part of \(SL_{2n}\). Now, \(V\) is the standard representation of \(SL_{2n}\) and \(V \otimes V\) contains the irreducible representation \(\text{Sym}^2(V)\). The restriction of \(\text{Sym}^2(V)\) to \(S_{\mathfrak{sp}_{2n}}(\mathbb{C})\) contains the representation \(U\), and \(v_{2\omega_n}^+\) is exactly the highest-weight vector of \(\text{Sym}^2(V)\). By Remark 3.4, we can choose weight vectors \(z \in \text{Sym}^2(V)\) such that \(\langle z, x \cdot v_{2\omega_n}^+ \rangle > 0\) for all \(x\) which are totally positive in the unipotent of \(SL_{2n}\). It follows that \(\langle z, x \cdot v_{2\omega_n}^+ \rangle > 0\) for \(x \in U_{>0}\).

Under the inclusion \(U \subset Z\), the vector \(z\) is a linear combination of \(v_\lambda \otimes v_\mu\) and \(v_\mu \otimes v_\lambda\) by Lemma 13.1(2). Here \(\lambda, \mu \in W \cdot \omega_n\), and if \(\lambda = w \cdot \omega_n\), then \(v_\lambda = \hat{w} \cdot v_{\omega_n} \in V\) and similarly for \(\mu\). We have \(z = \text{Av}_\lambda \otimes v_\mu + \text{Bu}_\mu \otimes v_\lambda\) for numbers \(A, B\). Using Lemma 13.1(3), we obtain that
\[
0 < \langle z, y \cdot v_{2\omega_n}^+ \rangle_U = \langle \text{Av}_\lambda \otimes v_\mu + \text{Bu}_\mu \otimes v_\lambda, y \cdot (v_{\omega_n}^+ \otimes v_{\omega_n}^+) \rangle_Z = \langle (A + B)v_\lambda, y \cdot v_{\omega_n}^+ \rangle_V \langle v_\mu, y \cdot v_{\omega_n}^+ \rangle_V
\]
Now \(A, B\) do not depend on \(y\). If we let \(y = x \in U_{>0}\), we deduce that \(A + B > 0\) since \(\langle v_\lambda, x \cdot v_{\omega_n}^+ \rangle_V\) and \(\langle v_\mu, x \cdot v_{\omega_n}^+ \rangle_V\) are both positive. It follows that \(\langle v_\lambda, y \cdot v_{\omega_n}^+ \rangle\) and \(\langle v_\mu, y \cdot v_{\omega_n}^+ \rangle\) have the same sign whenever \(\lambda, \mu \in W \cdot \omega_n\), and \(\lambda, \mu \in W \cdot \omega_{n-1}\). By Lemma 13.1(1), for any \(\lambda \in W \cdot \omega_n\), we have that \(\langle v_\lambda, y \cdot v_{\omega_n}^+ \rangle\) has the same sign as \(\langle v_{\omega_n}^+, y \cdot v_{\omega_n}^+ \rangle = 1\). This concludes the proof in the \(C_n\) case.

### 13.4. Type \(D_n\).
We take as simple roots \(\alpha_1 = \varepsilon_1 + \varepsilon_2\) and \(\alpha_k = \varepsilon_k - \varepsilon_{k-1}\) for \(2 \leq k \leq n\). Let us consider the (spin) representation \(V = V_{\varepsilon_1, \mathbb{R}}\) with highest weight \(1/2(\varepsilon_1 + \varepsilon_2 + \cdots + \varepsilon_n)\). The argument is the same as for \(C_n\) (using also Remark 3.4), after applying Lemma 13.1 to \(\omega = \omega_1\) and \(\eta = 2\omega_1 - \alpha_1 = \omega_3\). Note that \(2\omega_1\) is allowable.

### 13.5. Type \(E_6\).
The index of connection of \(E_6\) is 3, which is odd. The proof for \(A_n\) with \(n\) even can be applied here essentially verbatim.

### 13.6. Type \(E_7\).
We fix a labelling of the Dynkin diagram by letting 7 label the minuscule node (at the end of the long leg), and 6 be the unique node adjacent to 7. The argument is the same as for \(C_n\) (using also Remark 3.4), after applying Lemma 13.1 to \(\omega = \omega_7\) and \(\eta = 2\omega_7 - \alpha_7 = \omega_6\). Note that \(2\omega_7\) is allowable.

### 13.7. Types \(E_8, F_4,\) and \(G_2\). The adjoint group is simply-connected, so there is nothing to prove here.
Appendix A. Quantum Schubert positivity implies affine Schubert positivity in type $C$

We shall need the quantum Chevalley formula of $qH^*(G/B)$, due to Peterson [32] and Fulton-Woodward [11].

For $w \in W$, define $\pi_P(w) := w_1$, where $w = w_1w_2$ with $w_1 \in W^P$ and $w_2 \in W_P$. Also we have that $2\rho$ is the sum of positive roots and set $2\rho_P := \sum_{\alpha \in \Delta_{P,+}} \alpha$. Let $Q_P^\vee$ be the sublattice of $Q^\vee$ spanned by the simple coroots $\alpha_j^\vee$ for $j \in I_P$, and let $\eta_P : Q^\vee \to Q^\vee/Q_P^\vee$ be the natural projection. We let $w \succ v$ denote a cover in Bruhat order.

**Theorem A.1** (Quantum equivariant Chevalley formula [32, 11]). Let $i \in I^P$ and $w \in W_P$. Then we have in $qH^*(G/P)$

\[
\sigma_i^P \sigma_w^P = \sum_{\alpha} \langle \alpha^\vee, \omega_i \rangle \sigma_{\pi_P(w)r_\alpha}^P + \sum_{\alpha} \langle \alpha^\vee, \omega_i \rangle \eta_P(\alpha^\vee) \sigma_{\pi_P(wr_\alpha)}^P
\]

where the first summation is over $\alpha \in \Delta_P^+$ such that $wr_\alpha \succ w$ and $wr_\alpha \in W_P$, and the second summation is over $\alpha \in \Delta_P^+$ such that $\ell(\pi_P(wr_\alpha)) = \ell(w) + 1 - \langle \alpha^\vee, 2(\rho - \rho_P) \rangle$.

It is known that in the second summation, we only need to sum over $\alpha$ such that $\ell(r_\alpha) = \langle \alpha^\vee, 2\rho \rangle - 1$.

We now let $G$ be of type $C_n$. We choose conventions so that the $\alpha_1, \ldots, \alpha_{n-1}$ are short and $\alpha_n$ is long. One may check that the positive coroots $\alpha^\vee$ satisfying $\ell(r_\alpha) = \langle \alpha^\vee, 2\rho \rangle - 1$ are exactly those of the form $\alpha_i^\vee + \alpha_{i+1}^\vee + \cdots + \alpha_j^\vee$.

**Proposition A.2.** Conjecture 7.2 holds in type $C_n$.

**Proof.** Since we already know that we have $X_{>0}^G = X_{>0}^G$ and $X_{>0}^G \subseteq X_{>0}^{q\text{Schubert}}$, it suffices to show that any quantum Schubert positive point is also affine Schubert positive. By Theorem 6.4, it suffices to show that if $x \in X_{>0}^{q\text{Schubert}}$ then $q_i(x) > 0$ for each $i \in I$.

Now let $i \in I$, and let $v_i$ be the longest element in $W_P$, where $P_i$ is the maximal parabolic labeled by $i$. Let us consider the product $\sigma^{v_i} \sigma^{v_i}$ and apply Theorem A.1 for the base $P = B$. Since $v_i \alpha < 0$ for any $\alpha \in \Delta_P^+$, we see that the first summation of (A.1) is empty. We note that $\ell(v_i r_\alpha) = \ell(v_i) - \ell(r_\alpha)$ if and only if $r_\alpha \in W_{P_i}$. The only such coroots $\alpha^\vee$ which also satisfy $\ell(r_\alpha) = \langle \alpha^\vee, 2\rho \rangle - 1$ are $\alpha_i^\vee$ and $\beta_i^\vee := \alpha_i^\vee + \cdots + \alpha_n^\vee$ in the case $1 \leq i \leq n - 1$, and if $i = n$ we only have $\alpha_n^\vee$. Thus we obtain

\[
\begin{align*}
\sigma^{s_i} \sigma^{v_i} &= q_i \sigma^{v_i, s_i} + q_i q_{i+1} \cdots q_n \sigma^{v_i, r_{\beta_i^\vee}} & \text{for } i \neq n \\
\sigma^{s_n} \sigma^{v_n} &= q_n \sigma^{v_i, s_i} 
\end{align*}
\]

It follows that if $\sigma^w(x) > 0$ for all $w \in W$ then $q_i(x) > 0$ for all $i$. \qed
