Keywords: long-term care financing, institutional long-term care, ageing, China
Abstract

A rapid ageing population coupled with changes in family structure has brought about profound implications to social policy in China. Although the past decade has seen a steady increase in public funding to long-term care (LTC), the narrow financing base and vast population have created significant unmet demand, calling for reforms in financing. This paper focuses on the financing of institutional LTC care by examining new models that have emerged from local policy experiments against two policy goals: equity and efficiency. Three emerging models are explored: Social Health Insurance (SHI) in Shanghai, LTC Nursing Insurance (LTCNI) in Qingdao, and a means-tested model in Nanjing. A focused review of academic and grey literature is conducted to identify and assess these models, supplemented with qualitative interviews with government officials from relevant departments, care home staff and service users. This paper argues that, although SHI appears to be a convenient solution to fund LTC, this model has led to systematic bias in affordable access among participants of different insurance schemes, and has created a powerful incentive for the over-provision of unnecessary services. The means-tested method has been remarkably constrained by narrow eligibility and insufficiency of funding resources. The LTCNI model is by far the most desirable policy option among the three studied here, but the narrow definition of eligibility has substantively excluded a large proportion of elders in need from access to care, which needs to be addressed in future reforms. This paper proposes three lines of LTC financing reforms for policymakers: 1) the establishment of a prepaid financing mechanism pooled specifically for LTC costs; 2) the incorporation of more stringent eligibility rules and needs assessment; and, 3) reforming the dominant fee-for-service methods in paying LTC service providers.
1. Introduction
Ageing populations pose serious challenges for the health and long-term care (LTC) systems in China where demographic shifts are rapid and exacerbated by the former one-child policy. Concerns have arisen as to the well-being and support for the elderly, a substantial and growing share of China’s population and one that faces particular problems. In China, the total number of those aged 60 and above stood at approximately 180 million, or 13.3% of the entire population in 2011; known as the ‘oldest old’, the subgroup of the elderly aged 80 and above grew to approximately 11.95 million, accounting for nearly 12% of the elderly population (National Bureau of Statistics of China 2011).

Rooted in the ethics of filial piety, LTC in China has been largely reliant on family care; however, recent demographic shifts and socioeconomic changes have made it increasingly difficult for families to fulfil traditional duties. Although the government has been actively promoting home and community-based LTC programmes, progress has been rather slow, largely owing to a lack of resources and poor infrastructural capacity.

Over the past two decades, institutional LTC services have been booming in China to meet the escalating demands of the ageing population. Prior to 2000, institutional LTC facilities were predominantly managed and financed by the government. The characteristics of users and the sources of revenues started to change from the early 2000s. The mix of facilities has expanded to a wider spectrum, ranging from board-and-care residential care homes to modern nursing homes with skilled carers, nurses, doctors and medical services. Depending on regions and types of care, government-run care home services are typically financed through taxation and lottery funds as well as private payments (Tian 2005, Chen 2013). Although services are subsidised by the government, many complain that associated care costs are often too high. In 2005, nearly 60% of the elderly (about 3.5 million) did not seek care when needed, and this number is predicted to increase to 16 million by 2050 (Chen 2013, Gu, Vlosky 2008). Therefore, improving access to LTC and reducing its financial burden constitutes the first and foremost imperative for Chinese policy-makers.
In recognition of the growing needs of the elderly population, a number of local governments have embarked on LTC financing reforms since the 2000s. While these models vary in focus and scope, they share the same objective: to improve equitable access and reduce the financial burden experienced by service users. In particular, Shanghai has started to reimburse nursing care through Social Health Insurance (SHI) at designated nursing homes. Although China does not have national LTC insurance, Qingdao, a coastal city in Eastern China, introduced the country’s first LTC Nursing Insurance (LTCNI) in 2012, which covers home and community-based LTC services, as well as residential and nursing care services in designated facilities for urban-based elderly people with severe needs. Moreover, Nanjing, the provincial capital of Jiangsu Province, has adopted a means-tested model for institutional LTC, targeted at the poor elderly, known as the “Three Nos”\(^1\) and the “Five guarantees”.\(^2\)

While these new models represent the government’s efforts to improve access to affordable institutional LTC, solid assessments are scant. This paper aims to assess the new models represented by the reforms of Shanghai, Qingdao and Nanjing against two main principles: equity in access to care and efficiency in care provision. China’s distinct approach of social policy-making often involves a number of pilots in pioneer cities before the central authorities incorporate experiences proved to be successful into the national policy framework. This paper contributes to the ongoing policy discussion in searching for viable financing mechanisms to meet the mounting LTC needs by analysing cases from three representative Chinese cities.

The paper proceeds as follows. The first section outlines the background of LTC needs, provision and financing in China. An analytic framework, which synthesises evidence of LTC financing models in developed countries, is developed to guide the analysis in later sections; this is followed by methods and data collection. The third section discusses each financing model. The fourth section critically

---

1 Three Nos: Urban people with no children, no income and no relatives.
2 Five guarantees: Disabled rural people who have no income, no children or relatives to take care of them.
appraises the potential and pitfalls of these new models, and the final section lays out future directions towards an equitable and efficient LTC financing system in China.

2. Long-term care in China

2.1 Ageing population and the need for LTC

The Chinese population is undergoing rapid ageing; the median age reached 34.6 in 2010 and will climb to 46.3 by 2050 (Figure 1). The fast ageing population is associated with a dramatic rise in the prevalence of old-age conditions requiring both health and social care services. According to the National Commission on Ageing, approximately 12.4% of the urban elderly and 18.6% of the rural elderly are reported to have more than one Activity of Daily Living\(^3\) (ADL) affected (National Committee on Ageing, 2012). Other studies, including the China Health and Retirement Longitudinal Study (CHARLS), reported similar findings (Peking University 2013) (Table 1).

\(<\text{Figure 1 about here}>\)

\(<\text{Table 1 about here}>\)

2.2 LTC service provision

Long-term care is defined as “a set of services provided on a daily basis, formally or informally, at home or in institutions, to people suffering from a loss of mobility and autonomy in their activity of daily living” (Costa-i-Font 2011). In China, informal care provided by family at home is rooted in the norm of filial piety, and is still the predominant pattern of care provision in China. However, recent demographic shifts and socioeconomic changes are eroding this tradition. The increase in social mobility and the number of people now considered to be old have created difficulties for people to fulfil traditional filial duties towards their elderly parents. In addition, due to smaller families with fewer children, the availability of family members to provide care and support to elderly parents is

\(^3\) Routine activities that people tend to do every day without needing assistance. There are six basic ADLs: eating, bathing, dressing, toileting, transferring (walking) and continence. An individual’s ability to perform ADLs is important for determining the type of long-term care required (e.g. nursing-home care or home care).
also decreasing. In urban areas, the emerging ‘4-2-1’ family structure (four grand-parents, two parents, and one child) is emblematic of the potential problem. In rural areas, rural to urban migration in the 1990s has meant that elderly parents and grandparents living in rural areas are now geographically remote from their children. Co-residence by elderly rural-dwellers with their adult children fell from 70% in 1991 to 40% by 2006 (World Bank 2012). In 2011, only 8.5% of the disabled elderly received informal care from family members (Peking University 2012). Chinese families—the traditional bedrock of old-age support—are increasingly strained as the number of older people grows while the number of potential caregivers shrinks (Feng, Liu et al. 2012).

Recent years have seen increased government efforts to strengthen the capacity of LTC provision with infrastructural projects. Multiple strategies are in play, ranging from state-built/state-owned facilities to privately operated facilities with government support and subsidies for construction and operations (Feng, Liu et al. 2012, National Committee on Ageing, 2012). By 2012, China had 45,000 institutional care facilities and 4.3 million care home beds. The number of beds per 1,000 elderly reached 22.24 in 2011 (Feng, Liu et al. 2012).

China’s institutional LTC facilities can be categorised into three types, with Elderly Care Welfare Institutions (ECWI) being the most common. Similar to assisted living facilities or board-and-care homes, ECWIs used to admit those who qualified as ‘Three Nos’ or ‘Five Guarantees’, but began to accept private-payers from the late 1990s. Service users are typically provided with a furnished room, together with meals, housekeeping and laundry services. Assistance with daily activities such as personal hygiene, dressing, eating and walking is also provided (Fang 2013). The second type is nursing homes that started to boom in the 2000s, in response to the rising demand for specialised LTC. Nursing homes are intended for people who require continual nursing care and have significant difficulty in coping with normal activities in daily living. The third type is acute LTC care facilities that are usually affiliated to acute care hospitals and provide intensive treatment for elderly people with critical conditions.
2.3 LTC financing

LTC financing in China is a mixed system. Institutional LTC services under the existing arrangement are predominantly publically financed (i.e., government revenue and welfare lottery funds) as well as privately-funded places. The public part of the funding is used for capital investment, labour costs, as well as various operational expenses (The State Council of P.R. China, 2013). The central government has required local governments to secure sufficient funds for LTC. It is also stipulated that at least half of the surplus earned by the welfare lottery funds must be earmarked for the development of LTC systems (The State Council of P.R. China, 2011, The State Council of P.R. China, 2013). In Zhejiang Province, for instance, the Welfare Lottery generated revenue of RMB 510 million in 2014, from which RMB 226 million was injected to support LTC services. Public facilities alone received RMB 60 million to meet construction costs (The Chinese Society Newspaper, 2015).

Public funding constitutes the major source of LTC financing in China, but this single source is far from sufficient. A large proportion of costs is still paid out-of-pocket by service users themselves, and unmet needs are high among the disabled elderly. In 2013, approximately 11.3% of the disabled elderly, aged 60 and above, reported receiving no care at all in urban areas, and the percentage was 13.2% in rural areas (Yang 2014, Yang, Wu 2014).

3. Methods

3.1 Analytical framework

Despite the country’s reliance on taxation and lottery funds to finance institutional LTC, new models have emerged, aiming to improve affordable access to care. This paper provides an initial evaluation of new financing models against two main policy objectives—equity and efficiency. Specifically, we are interested in understanding 1) how different financing models affect equitable access to care, and 2) efficiency in care provision (Mossialos, Dixon 2002).
To guide our analysis, an analytical framework that synthesises evidence of LTC financing models in developed countries is developed. Three broad models in public financing of LTC are: a SHI providing universal coverage, LTC insurance dedicated to financing LTC treatment, and a means-tested model with more lenient eligibility criteria based on income and assets. Specifically, SHI offers universal coverage and financial protection against catastrophic out-of-pocket costs, and has the advantage of using market power to negotiate payment (Mossialos, Dixon 2002); however, coverage of services is usually limited to nursing care, and co-payments are often required (Willeme, Geers et al. 2012). Separate from SHI, LTC insurance is a dedicated, stand-alone insurance arrangement for LTC services (Schut, van den Berg 2012, Chon 2012, Zuchandke, Reddemann et al. 2012). The advantages of LTC insurance lie in that it is designed specifically to cover a broad range of LTC services. However, issues related to entitlements and needs assessment are not always properly addressed (Schut, van den Berg 2012, Costa-Font, Courbage 2012). The means-tested model provides a safety net for those who are unable to pay for LTC, but this model may leave the elderly impoverished before becoming eligible, and are more prone to budget cuts or cash constraints (Comas-Herrera, Wittenberg et al. 2012).

Table 2 exhibits the advantages and disadvantages of the three financing models against the objectives of equity and efficiency. The table serves as an analytical framework that guides the analysis of the three new financing models in later sections.

3.2 Case selection and data collection

A multi-faceted approach incorporating three data streams is used for this paper. This includes: 1) A systematic narrative review of Chinese government documents; 2) a review of academic literature; and, 3) a series of semi-structured interviews.
First, a systematic narrative review was conducted in order to comprehensively summarise the available evidence on policy development in LTC financing in China over recent years. Systematic narrative reviews are a hybrid method of a systematic literature search that incorporate narrative syntheses and analyses. The review component involved a search of the websites of key governmental organisations, including the Ministry of Civil Affairs and the National Health and Family Planning Commission and their provincial bureaus to identify policy developments on LTC financing at both national and provincial levels. The (Chinese language) grey literature, particularly central and local government reports, were also reviewed. This was deemed appropriate as peer-reviewed academic literature on the topic is limited and there is a substantial body of grey evidence available. This review led to the identification of three new LTC financing reforms in three cities that were selected for further review and investigation, including Shanghai (SHI), Qingdao (LTCNI) and Nanjing (means-testing). Shanghai was chosen because it is one of the first of few cities in China to use SHI to fund institutional LTC. Qingdao is the only city that has instituted a dedicated LTC insurance scheme in China. Adopted by Nanjing, the means-tested method is also considered as representative. This selection of cases was by no means exhaustive, but it mainly sought to identify new financing initiatives that represent the direction of the ongoing policy experiments at local level. After the case cities were selected, the grey literature at the local government level was reviewed, and evidence was synthesised and analysed.

Second, English and Chinese academic search engines were used, i.e., Web of Knowledge, EBSCO, ScienceDirect, and Chinese National Knowledge Infrastructure (CNKI), to identify peer-reviewed publications on these three models. Three types of scholarly papers, including empirical evaluation, policy analysis and perspective papers published from 2000 to 2015 were reviewed. The key words used in each of the search engines were: ‘China & LTC & financing’, ‘China & LTC & funding’, ‘China & elderly* care & financing’ (or equivalent in Chinese). We excluded articles that are not on China and LTC financing. A total of 42 studies, including both grey literature and academic articles, were reviewed. A flowchart summarising the article selection process can be found in Appendix 1.
This paper also draws on insights and materials from a series of qualitative interviews with three groups of informants in the study cities: government officials from relevant departments, care home staff, and service users. Interviews were used to identify major gaps in knowledge or to identify key government documents. Interview questions included those from a social, economic and political context in which LTC facilities operate, new financing policy models, challenges and barriers to the development of an institutional LTC. Sixteen semi-structured interviews were conducted between December 2013 and December 2014. A brief interview guide can be found in Appendix 2.

LTC financing models for institutional care in China are constantly evolving, and this paper only presents the situation as of 2014.

4. Results

4.1 New LTC financing models

This section discusses how each new approach is implemented based on the practices in Shanghai, Qingdao and Nanjing. Key features of these models are summarised in Table 3. A flow chart that illustrates the financing process of institutional LTC of both old mechanisms and new models can be viewed in Figure 2.

<Figure 2 about here>

Model 1: Social Health Insurance (the case of Shanghai)

Financing LTC costs through the health care system often means that LTC is viewed as a health risk, and institutional arrangements reflect the ‘medical’ element of care delivery. In order to cope with the mounting needs of the elderly population, Shanghai started to reimburse LTC costs incurred at specialised nursing homes from its SHI scheme from the mid-2000s (Shanghai Civil Affairs Bureau 2013, Shanghai Civil Affairs Bureau 2015). Three SHI schemes coexist in China: The Urban Employee Basic Medical Insurance (UEI) covers urban residents with formal employment before retirement; The Urban Resident Basic Medical Insurance (URI) covers uninsured urban residents,
including the disabled and university students; and for the rural elderly, care is reimbursed through the New Cooperative Medical Scheme (NCMS)—a county-level voluntary risk-pooling scheme subsidised by the government. Depending on the type of services, the elderly in Shanghai are eligible for reimbursed LTC costs through SHI. The reimbursement is, however, limited to costs incurred at government-run nursing care facilities, whereas care provided at ECWIs is not covered by SHI. Until April 2015, there had been no clear requirement for a needs assessment for admission to nursing homes (Shanghai Health and Family Planning Bureau, Shanghai Civil Affairs Bureau et al. 2015).

Even though LTC costs are reimbursable via SHI in Shanghai, only standard medical costs are covered, such as medication, physiotherapy, examination and bed costs. Meals (around RMB 20 per day) and carer costs (around RMB 50-70 per day) must be paid out of pocket (Development and Reform Commission Shanghai, Shanghai Finance Bureau 2014). Heavily subsidised by the Shanghai Government, the three SHI schemes, however, vary significantly in terms of co-payments. Our in-depth interviews suggest that the reimbursement rate for the UEI is up to 92%, with an excess of RMB 700. Elders are also eligible for a supplementary insurance plan that offers a further reduction for the remaining 8% of costs. The reimbursement rate under NCMS is up to 75% with no excess. The URI offers two types of reimbursement rates. For those who moved to urban areas because of land acquisition, the reimbursement rate is up to 80% with an excess of RMB 1568 while for ordinary urban residents without formal employment the URI reimburses up to 90% with an excess of RMB 50.

While elderly members of the URI scheme need to pay a fixed annual premium of RMB 340, their counterparts in UEI and NCMS are not obliged to pay contributions after retirement.

Despite the portability of SHI at all government-run nursing homes in the city, the number of such facilities remains low in contrast to rising demand. Accounting for more than 27% of the city’s population, the elderly population reached 3.87 million in 2012. In contrast, there were only 64 government-run nursing homes among the 615 LTC facilities in Shanghai in 2012 (Fang 2013, Shanghai Civil Affairs Bureau 2015).
Model 2: Social LTC Nursing Insurance Model (the case of Qingdao)

LTC insurance is a stand-alone system dedicated to LTC services. Qingdao, a coastal city in Eastern China, is experiencing rapid ageing and is the first Chinese city to introduce social LTC insurance. Officially launched in 2012, LTCNI is separate from SHI and is dedicated to covering only LTC services at designated care providers. Distinct from most LTC insurance programmes in other societies, the LTCNI scheme in Qingdao is subsidised by the municipal government and draws funds from SHI. It requires no individual or employer contributions (or premiums) (Qingdao Human Resource and Social Security Bureau 2014). However, eligible participants must satisfy a number of criteria. First, only elderly people who were previously enrolled in UEI or URI are eligible to participate. Second, this insurance is only available for those who have critical LTC needs (usually bedridden) and are in need of either long-term professional institutional care or home care. A needs assessment, which includes a number of questions on Activities of Daily Living (ADL), is performed to determine eligibility (Municipal government of Qingdao, P.R. China 2012).

Once an elderly person is enrolled in the insurance, four types of care are available for them to choose from: 1) home-based nursing care, 2) community-based care, which involves regular home visits, 3) residential or nursing care offered at designated facilities, and 4) acute hospital care provided at a tertiary hospital (Yuan 2013b, Municipal government of Qingdao, P.R. China 2012). Irrespective of the type of care an elderly person chooses, all care providers are required to create detailed care plans for each service user, from assessment, referral, monitoring their condition to the provision of end of life care.

In terms of financing, LTCNI is jointly financed by welfare lottery funds operated by the government as well as by earmarked contributions from both the UEI and URI. SH schemes. Specifically, 0.2% of UEI funds are accrued to LTCNI funds every month, which also draw from the URI on an annual basis, up to 0.2% of the disposable income of urban residents in Qingdao. In addition to sources from SHI, a total of RMB 20 million or US$3.24 million is injected to LTCNI from the government’s
Public Welfare Funds\(^4\) each year. In fact, a total of RMB100 million was allocated from the funds to the LTCNI as an endowment when it was initially launched (Qin, Li et al. 2014, Qingdao Human Resource and Social Security Bureau, Qingdao Finance Bureau et al. 2012b).

Services are purchased by the LTCNI from designated providers at fixed costs. Prices are fixed at RMB60 per day for home-based services or services at designated care homes. Daily rates are fixed at RMB170 to RMB200 for care provided at tertiary hospitals. The insurance reimburses 96% of the costs for home-based or care home services, and 90% for tertiary care (Municipal government of Qingdao, P.R. China 2012). The elderly are responsible for the remaining of the fees.

Apart from the LTCNI pilot programme, the Qingdao government has also made concerted efforts to expand LTC services and facilities since 2012, including 244 organisations providing home-based care, 29 designated residential and nursing facilities, and nine tertiary care units. Carers are trained in government facilities to provide high-quality professional care.

**Model 3: Means-testing (the case of Nanjing)**

Means-testing is commonly used to determine the amount of user cost sharing by taking a set of criteria, such as income and assets. This approach offers a safety net for those who would otherwise be unable to afford care. Unlike Shanghai where LTC costs in nursing facilities can be partially reimbursed through SHI schemes, in Nanjing, the financing of public LTC is mainly through the distribution of care vouchers or other types of subsidies using a means-tested method (Nanjing Civil Affairs Bureau 2006). In 2014, the Nanjing Government issued a number of policy directives on improving equitable access to LTC. The government provides monthly subsidies in the form of vouchers to those who fall into the following categories: ‘Three Nos’, ‘Five guarantees’, those falling below the poverty line or with substantial/critical care needs, those aged 70 and above without children, and so on. The voucher amounts to between RMB 300 and RMB 400 per month and can be

\(^4\) The Public Welfare Fund is the profit raised by the Chinese Welfare Lottery. The government is responsible for distributing the fund, and this money usually goes to welfare projects that improve health, education and the well-being of the population.
used to pay for care provided by designated home care providers. It can also be used to pay for an informal carer, usually their children or spouse. However, informal carers are required to attend relevant training courses before they can be paid by the government (Jiangsu Civil Affairs Bureau 2014). If the elderly person needs to continue care in an EWCI or a nursing facility, he or she can use the voucher to pay for services at preferred care facilities. Priority of admission to a government-run LTC facility is given to the aforementioned eligible groups; for the ‘Three Nos’ and ‘Five guarantees’ group, expenses incurred at these facilities are fully subsidised. If no bed is available at a nearby government-run LTC facility, the government has the responsibility to purchase services at a private facility to ensure that the needs of ‘Three Nos’ and ‘Five guarantees’ are adequately addressed (Nanjing Civil Affairs Bureau 2014a, National Business Daily, 2015). For the poor elderly with severe physical disability or cognitive impairment, a subsidy towards institutional care costs is usually available from the government in addition to the voucher amount (Nanjing Civil Affairs Bureau 2014a).

The Nanjing government has also been actively promoting the construction of LTC facilities. Depending on the location, a facility may receive a lump-sum subsidy of between RMB4000 and 6000 per new bed, and a maintenance subsidy of between RMB500 and 1200 per bed every five years. In order to encourage care facilities to admit elderly with greater care needs, a monthly subsidy of RMB120 to 150 per person is provided. Nanjing had 264 LTC facilities and 48,000 beds by 2015; the figures are expected to increase to 645 facilities and 83,800 beds respectively by 2020 (National Business Daily, 2015).

4.2. A critical assessment of the new financing models

The new financing initiatives in Shanghai, Qingdao and Nanjing have offered rich lessons for the rest of China as they involve different strengths and limitations from which other regions can learn while
designing their own financing options. In this paper, each financing model is assessed against two policy objectives: equitable access to care and efficiency in service provision.

4.2.1 How does the financing model affect equitable access to care?

**SHI**

SHI covers LTC costs at specialised nursing facilities and partially reduces the financial burden of the elderly. There is significant inter-generational redistribution between the working population and the retired, with the latter paying much less or none in SHI premium. However, there are significant differences in reimbursement rates, contribution rates and excesses across SHI schemes, which lead to systematic inequity among different groups of the population. In the case of Shanghai, for instance, the reimbursement rate for the NCMS is 75%. For the majority of rural residents who only receive a fixed pension (around RMB600-700 per month), the out-of-pocket payments are often unaffordable (Shanghai Civil Affairs Bureau 2015, Fang 2013). Similarly, high co-payments and contribution rates also create access barriers for URI participants, who have low incomes and savings due to unemployment. Interviews with nursing home staff in Shanghai suggest that the majority of nursing home users are UEI participants. Due to the absence of pre-admission needs assessments, better-off UEI participants with lower needs have a much greater chance of admission, *vis-a-vis* their URI or NCSM counterparts who may have more needs but are usually deterred by the high costs of nursing homes.

**LTCNI**

The LTCNI in Qingdao has insured more than 16,000 across the elderly population, with an average age of 78 as of 2013. Some initial assessments show that the insurance has significantly improved access and reduced care costs (Qin, Li et al. 2014). The elderly need to go through a strict needs assessment before becoming eligible and no premium or excess is required upon enrolment. Compared to SHI, the design of the LTCNI guarantees equitable access to LTC for the urban elderly irrespective of individual socioeconomic characteristics, such as employment and economic status.
However, the LTCNI has a number of limitations with regards equitable access to care. First, participants have to be ‘bed-ridden’ and in 2013, the number with substantial or critical needs in Qingdao stood at approximately 250,000, among which only one third were deemed ‘bed-ridden’. Thus, the current eligibility criterion has essentially excluded two thirds of the elderly population with substantial needs. For instance, evidence from our interviews indicates that costs for those who suffer from severe cognitive impairment tend to be even higher than those for the bed-ridden elderly. This group are ineligible for the insurance, and their care costs are largely shouldered individually or by family members (Zhao 2015, Zhu, Tan 2015). Second, the LTCNI only covers the urban elderly (Qingdao Human Resource and Social Security Bureau 2014, Nanjing Civil Affairs Bureau 2014b), while the vast rural population is excluded which accounts for 65% of the city’s population. Compared to their urban peers, the rural residents are comparatively poorer but are more likely to suffer from higher rates of mortality and morbidity (Zimmer, Wen et al. 2010). This entitlement bias has essentially excluded those with potentially greater needs and has exposed them to higher financial risk (Qingdao Human Resource and Social Security Bureau 2014). Lastly, meals or carer costs are met by the elderly who receive care home services, and these costs create greater financial hardship for poor users.

*Means-testing*

Means-testing is a type of financial support for those with severe needs and are unable to pay; however, its application in Nanjing is very limited in terms of both scope and capacity, and thus does not constitute a reliable safety-net. Although the Nanjing Government has broadened the eligibility criteria for the monthly care vouchers beyond the ‘Three Nos’ and the ‘Five Guarantees’, the value of the voucher is merely RMB300-400 per month, far below the average costs needed in an ECWI or nursing home. Similarly, the eligibility for fully-subsidised care at ECWIs or nursing facilities is tied
to the status of the ‘Three Nos’ or the ‘Five Guarantees’, which has also excluded a large proportion of the poor elderly.

4.2.2 How does the financing model affect efficiency in provision?

**SHI**

Efficiency measures, relate to resources used to obtain the best value for money (Palmer, Torgerson 1999). Similar to the situation in most Chinese hospitals, nursing homes in Shanghai are largely financed through a fee-for-service (FFS) system. Reliant on revenues from drugs and services, providers have a great incentive to charge more from those with SHI. As revealed by nursing home staff in Shanghai, a ‘sales target’ is imposed on both the facility and individual staff members. As most service users are covered by SHI, nursing facilities tend to provide a great deal of unnecessary care to meet the revenue target. Nursing home staff also suggested that the standard medical costs vary significantly depending on the amount of services an elderly person uses. Frequent use of physical examinations, daily physiotherapy and other related medical services can help care facilities to generate revenue, and this can lead to rapid cost escalation. Furthermore, the lack of effective purchasing mechanism limits means that the SHI cannot act as a purchaser to negotiate for higher quality and lower costs, which has largely undermined the technical efficiency of care provision.

**LTCNI**

In contrast to SHI, the LTCNI has an effective purchasing mechanism that purchases care and negotiates prices with providers for fixed costs. Hence, providers have fewer incentives to over-providing services. The *per diem* rate is fixed at RMB60 at designated ECWIs, and at RMB170 at secondary nursing homes, and lastly RMB200 at tertiary care units, whereas the costs of equivalent services are set at RMB 498 for secondary hospitals, RMB 1,072 for tertiary hospitals, and RMB 4,641 for Intensive Care Units. As such, the LTCNI is better able to contain costs. The LTCNI also covers home-based care services at very low costs (RMB60 per day) (Qin, Li et al. 2014). Although evidence on how the provision of home-based care affects hospital and care home admissions is rather limited in the Chinese context, examples from western countries suggest that professional home care
has ‘substitution effects’, which may reduce admissions to secondary and tertiary hospitals, and costs associated with these admissions and health care afterwards (Forder 2009). One concern with regards to the efficiency of LTCNI is that, although the LTCNI has a strict needs assessment, the scheme does not specify how it facilitates or hinders the movements from home-based care to residential or nursing facilities, without which, the type of care received largely depends on an individual’s preferences or ability to pay, rather than actual care needs, hence introducing problems related to both equity and efficiency (Jiang, Ma et al. 2014, Yuan 2013a).

**Means-testing**

The efficiency of the means-tested approach depends on how the criteria of the target population are defined, and whether the funding can reach the target population efficiently. However, as our interviews suggest, there is a lack of clarity and transparency in practice, particularly related to the complexity of eligibility criteria and coverage of services. Interviews with government officials noted that although Nanjing has made its first step to combine both needs assessments and means-tests in the definition of eligibility to receive subsidised care, technical difficulties remain in practice. For instance, eligibility is vaguely defined as ‘being poor’, and there is no strict means-test. Even care home workers or service users are often confused by related criteria. These weaknesses have brought about major challenges to efficient targeting.

5. **Discussion and conclusion**

A rapidly ageing population, coupled with changes in family structure, has brought about profound implications to social policy in China. Although the past decade has seen a steady increase in public funding to LTC, the narrow financing base and vast population combined has resulted in a large unmet demand - calling for financing reform. This paper focused on institutional LTC care by examining three new models that have emerged from local policy experiments. We assessed the pilot models from Shanghai, Qingdao and Nanjing against two dimensions: equity in access and efficiency in provision.
The Shanghai model represents efforts to absorb LTC expenditure within the existing SHI sources. This appears to be a convenient solution given the city’s rich experience in running SHI and the sizable insurance funds available. The analysis, however, has revealed that the fragmentation of SHI schemes has led to systematic bias in affordable access among participants of different schemes. Moreover, our analysis suggests that FFS, as the dominant method of paying providers, has created a powerful incentive for over-providing unnecessary services, thus leading to a significant waste of resources. This problem is also relevant to some other Asian countries (e.g. Singapore, Taiwan, Vietnam and India) with health systems based on the FFS payment method. These countries need to be cautious when introducing the FFS mechanism as a payment system in their LTC facilities because it may lead to cost escalation.

Public LTC insurance has been gaining currency in recent decades. While Japan and South Korea have instituted their respective LTC insurance systems, Taiwan is also moving towards this (Tamiya, Noguchi et al. 2011, Chon 2012, Nadash, Shih 2013). The pilot in Qingdao City echoes this regional trend. A special feature of this insurance scheme is that no separate (premium) contribution by beneficiaries is required. Our analysis, overall, found this model to be a desirable policy option; however, the narrow definition of eligibility has substantively excluded a large proportion of needy elders from gaining access to care, which needs to be addressed in future reforms.

The Nanjing model is characterised by a means-tested voucher system with a needs assessment. The analysis, however, has revealed that the actual implementation in Nanjing has been remarkably constrained by narrow eligibility and insufficient funding resources. For local governments, which have no plan to introduce LTC insurance, the means-tested voucher remains a convenient policy tool, but the actual design and operation requires strong administrative and financial capacity that may not be present in many localities.

The three models examined in this paper represent meaningful policy experiments in search of a suitable LTC financing model. Although the sheer size of China frustrates any attempt of a one-size-
fits-all financing model, several implications for LTC financing in China can be drawn. First, a financing mechanism for prepayment and pooling specific to LTC costs (be it the form of SHI or LTC insurance) needs to be established nationally - though how such a mechanism might work still requires more research. Second, eligibility rules and the extent of cost-sharing must incorporate strict needs assessments. Service coverage in China is limited to what public funding can provide, particularly when there is a shortage of revenue. LTC financing would continue to be cost-ineffective if public funds are targeted at those in the greatest need. Third, care providers need to move away from FFS payment arrangements. The example of Shanghai clearly illustrates that the FFS system, China’s predominant payment method for health care services, feeds the vicious cycle of cost escalation and leaves SHI participants vulnerable to price hikes and the unregulated overuse of services.

This paper provides an initial policy evaluation of new financing pilots in China. Yet it is important to keep in mind that LTC financing is highly decentralised in the country. The LTC insurance model assessed in the paper has taken place in wealthier coastal regions where stronger fiscal capacity allows local governments to embark on this policy intervention. A more thorough evaluation is needed in the search for a suitable LTC financing model in China.

Type of care | Provider/user | Mechanism | Source
--- | --- | --- | ---
ECWI | Provider | Taxation and lottery funds | Individuals, firms, corporate entities and employers
 | User | SHI | Individuals, households, employees and employers
Nursing facilities | Provider | LTCNI | UEI, URI and lottery funds
 | User | Means-testing | Government revenue
Acute LTC facilities | Provider | Out-of-pocket payments |
Appendix 1. Flowchart of article selection process

Identification

137 peer-reviews records identified (79 in English and 58 in Chinese) through database searching

34 duplicates removed (19 in English, 15 in Chinese)

103 records screened

Screening

52 additional grey literature (in Chinese) identified through other sources

83 records excluded after abstract review

Eligibility

20 full-text articles (3 in English and 17 in Chinese) assessed for eligibility

83 full-text articles excluded
- 7 not on China
- 76 not on LTC financing

20 peer review studies included

Included

22 grey literature studies included (in Chinese)

42 studies included

Note: Three English academic search engines, i.e., Web of Knowledge, EBSCO, and Science Direct, were used. And one Chinese academic search engine, i.e., Chinese National Knowledge Infrastructure was used. The key words used in each of the search engine were: ‘China & LTC & financing’, ‘China & LTC & funding’, ‘China & elderly* care & financing’, ‘长期照护&筹资’, and ‘养老照护&筹资’. The search was based on academic papers published between 2000 and 2015.
Appendix 2. Interview guide

Qualitative interviews with government officials from relevant departments, care home staff and service users in the study cities were conducted in a semi-structured format. All interviews were conducted in Chinese; however, none were recorded due to political sensitivity and in order to gain more candid answers. Information from the interviews is not attributed to specific individuals or care providers, as LTC financing is a politically sensitive topic in China. The names and roles of the informants are not disclosed to ensure the confidentiality of the data. Examples of the questions we asked are as follows:

1. General questions (For government officials, care providers):
   - Do you think the current financing model (SHIs, LTCNI, means-tested) of institutional LTC has sufficiently addressed the issue of unmet needs among the elderly in China?
   - In your opinion, what are the most significant challenges of the LTC system and LTC financing in China?
   - What are the priorities for your organisations in terms of providing efficient and equitable LTC?
   - What are the most significant challenges that your organisations have?
   - What is the government’s plan for developing further financing models of LTC?

2. Financing model questions (For care providers):

   **SHI/LTCNI**
   - What are the reimbursement rates, premiums and excess rates across different SHIs/LTCNI?
   - What LTC services can be reimbursed?
   - What services/items cannot be reimbursed? How much might these services/items cost per month?
   - Can you describe the role of the LTCNI in purchasing services?
Means-tested method

- How, in general, does a means-tested method operate?
- What are the eligibility criteria for receiving care vouchers?
- Can the vouchers be used in any of the government-run care providers?

3. Equity in financing questions (For government officials, care providers, service users):

- What are the main problems relating to equity in access to government-funded institutional LTC?
- Do the rural and urban elderly have the same access to care even when enrolled in different SHI schemes?
- Can the elderly afford out-of-pocket costs of care after the SHI/LTCNI reimbursement?

4. Efficiency in financing questions (For government officials, care providers, service users):

- Do you think all care services provided in the care home are good value for money?
- Will the doctors over-prescribe/over-provide services to those elderly with SHI/LTCNI coverage?
- Is admission to a care home based on any needs assessment? If so, how are needs assessed?

5. Affordability questions (For service users):

- Are you covered by any SHIs, LTCNIs, or any other sources of funding for your care? Do you think your current income (including pension and income from other sources) sufficiently enough to cover the OOP costs in a care home?
- Do you need to ask your children/relatives to pay your care costs?
