Summary
The programmed cell death 1 (PD-1) receptor plays a major role in regulating T cell activation. Our aim was to determine how inflammation influences PD-1-mediated T cell suppression. Flow cytometry analysis of rheumatoid arthritis (RA) and psoriatic arthritis (PsA) synovial fluid (SF) mononuclear cells showed an increase in the percentage of PD-1+ cells within the CD4+ and CD8+ T cell compartment compared to paired peripheral blood (PB). Upon in-vitro T cell receptor (TCR) stimulation of healthy control (HC) CD4+ T cells in the presence of plate-bound PD-L1fc chimera, significantly decreased proliferation and interferon (IFN)-γ secretion was observed. In contrast, CD4+ T cells from RA and PsA PB and SF appeared resistant to such PD-1-mediated inhibition. Addition of the proinflammatory cytokines tumour necrosis factor (TNF)α, interleukin (IL)-6 and IL-1β, which were increased in RA and PsA SF compared to osteoarthritis (OA) SF, consistently abrogated PD-1-mediated suppression in HC CD4+ T cell cultures. This effect was reversed by inhibitors of these cytokines. Soluble PD-1 (sPD-1) levels were increased in cell culture supernatants from TNFα and IL-6-stimulated cultures compared to untreated controls, and also in RA and PsA, but not in OA, serum and SF. Functionally, addition of sPD-1fc counteracted PD-1-mediated suppression of HC CD4+ T cells, and increased T cell proliferation in HC CD4+ T cell/monocyte co-cultures. These in-vitro findings indicate that CD4+ T cells from patients with RA and PsA show increased resistance to PD-1-mediated suppression, which may be explained in part by the presence of soluble PD-1 in the inflammatory environment.

Keywords: inflammatory arthritis, IL-6, PD-1, PD-L1, TNFα

Introduction
The programmed cell death 1 (PD-1) receptor, a transmembrane protein and member of the B7 family, plays a critical role in T cell regulation [1]. PD-1 is expressed on T cells, where its expression increases within the first 24 h of T cell activation and decreases with antigen clearance [2–4]. Upon ligation of PD-1 by its ligands (PD-L1/B7-H1 and PD-L2/B7-DC), T cell responses are down-regulated [5,6]. PD-1 ligation leads to inhibition of the phosphatidylinositol 3-kinase (PI3K) pathway, resulting in reduced Akt (protein kinase B) phosphorylation and reduced expression of transcription factors GATA-3, T-bet and Eomes [7,8]. The overall effect of PD-1 ligation is decreased T cell activation and cytokine production [9–12]. The clinical relevance of PD-1 in immune regulation is evidenced by the recent success of PD-1 blockade in the treatment of certain end-stage cancers, leading to reduced tumour burden and enhanced anti-tumour immunity in a considerable number of patients [13,14]. Conversely, in inflammatory conditions it has been documented that disruption of the PD-1 gene (pdc1d1) in mice leads to lupus-like syndrome, proliferative arthritis, diabetes, autoimmune cardiomyopathy and increased susceptibility to collagen-induced arthritis (CIA) [15–20]. In humans, polymorphisms in the PDCD1 gene have been associated with susceptibility to rheumatoid arthritis (RA), ankylosing spondylitis (AS), systemic lupus erythematosus (SLE), multiple sclerosis (MS) and type 1 diabetes mellitus [21–25].
Several investigators have shown that frequencies of PD-1<sup>+</sup> CD4<sup>+</sup> T cells are increased in RA synovial fluid compared to RA peripheral blood (PB) and healthy control (HC) PB [20,26,27]. However, despite high levels of this inhibitory receptor at the site of inflammation, the immune system seems unable to regulate persistent T cell activation and cytokine production. This poses the question as to whether the PD-1 pathway is impaired during inflammation. An indication of a defective PD-1 pathway in RA comes from a study indicating that RA synovial fluid (SF) CD4<sup>+</sup> T cells show reduced PD-1-mediated inhibition compared to RA PB cells [20]. This suggests that under conditions of chronic inflammation the PD-1 pathway is modulated. Thus far, little is known regarding the PD-1/ PD-L1 pathway in the context of psoriatic arthritis (PsA). PsA and RA, while sharing a number of common pathological features, are two distinct diseases with serological, genetic and radiological differences [28]. Here we determined the expression of PD-1 on T cells from PB and SF of patients with RA or PsA, and investigated how inflammatory mediators associated with RA and PsA affect PD-1-mediated T cell suppression. Our data indicate that CD4<sup>+</sup> T cells from patients with RA and PsA are compromised in their PD-1-mediated inhibition and reveal a potential role for soluble PD-1 (sPD-1) in the aberrant PD-1-mediated regulation in these diseases.

**Materials and methods**

**Patients and healthy volunteers**

Heparinized PB and matched SF samples were obtained from patients with RA and PsA recruited from the rheumatology out-patient clinic at Guy’s and St Thomas’ Hospital NHS Trust (London, UK). Information on clinical and demographic parameters is provided in Supporting information, Table 1. HC subjects were recruited from among local student and staff volunteers. Written informed consent was received from all participants. Ethics approval was obtained by the Bromley Research Ethics Committee (approval no. 06/Q0705/20) for HC, RA and PsA and by the Guy’s Research Ethics Committee (approval no. 01/05/01) for osteoarthritis (OA). All samples were collected in compliance with the Declaration of Helsinki.

**PBMC, SFMC and cell subset isolation**

PB mononuclear cells (PBMC) and SF mononuclear cells (SFMC) were isolated by Lymphoprep<sup>TM</sup> (Axis-Schield, Oslo, Norway) density-gradient centrifugation. Cell subsets were isolated by magnetic separation (Miltenyi Biotech, Bergisch Gladbach, Germany and Dynabeads Thermofisher, Paisley, UK) and purity was determined by flow cytometry. CD4<sup>+</sup> T cells (purity range 95–99%) were isolated by negative isolation from PBMC or SFMC or from the CD14-depleted cell fractions following the manufacturers’ instructions. CD14<sup>+</sup> monocytes (purity range 96–98%) were selected positively using CD14 MicroBeads (Miltenyi Biotec).

**Cell culture**

Cell subsets were cultured for 5 days in culture medium (RPMI-1640; Gibco, Paisley, UK), supplemented with 1% penicillin/streptomycin, 1% L-glutamine (Gibco) and 10% heat-inactivated fetal calf serum (Gibco) and maintained at 37°C and 5% CO₂ atmosphere. Cells were stimulated with either plate-bound anti-CD3 monoclonal antibody (mAb) (OKT3; Janssen-Cilag Ltd, High Wycombe, UK) (1·5 μg/ml) in CD4<sup>+</sup> T cell only cultures or with soluble anti-CD3 mAb (OKT3; Janssen-Cilag Ltd) (100 μg/ml) in CD4<sup>+</sup> T cell/CD14<sup>+</sup> monocyte co-cultures.

**Flow cytometry analysis of cell frequency and phenotype**

For ex-vivo analysis of frequency and phenotype of each cell subset, PBMC or SFMC were stained extracellularly for 30 min at 4°C using different combinations of the following antibodies: fluorescein isothiocyanate (FITC)-conjugated CD279 (PD-1; BioLegend, Cambridge, UK), phycoerythrin (PE)-conjugated CD274 (PD-L1; BD Pharmingen, Oxford, UK), PE/cyanin 7 (Cy7)-conjugated CD3 (BioLegend), peridinin chlorophyll (PerCP)/Cy5.5-conjugated CD4 (BioLegend), PacBlue-conjugated CD8 (BioLegend), allophycocyanin (APC)-conjugated CD8 (BioLegend) and Vio770-conjugated CD14 (Miltenyi Biotech). Following surface staining, cells were fixed in 2% paraformaldehyde (PFA) for 15 min at 4°C, washed twice and acquired on a BD fluorescence activated cell sorter (FACS)Calibur or a BD FACSCanTo II. Data were analysed using FlowJo software (version 7.6.5; Tree Star, Ashland, OR, USA).

**T cell proliferation and PD-1 ligation assays**

96 well flat-bottomed plates (Costar, Corning Inc., Corning, NY, USA) were coated with anti-CD3 mAb (OKT3; Janssen-Cilag Ltd) (1·5 μg/ml) and with either PD-L1fc or immunoglobulin (Ig)G1fc (R&D Systems, Abingdon, UK) (ranging from 0 to 5 μg/ml according to the experiment) in phosphate-buffered saline (PBS) solution (Sigma Aldrich, Poole, UK) for 4 h at 37°C and 5% CO₂. Plates were washed twice with PBS before cells were added for culture. CD4<sup>+</sup> T cells were isolated from cryopreserved HC PBMC, RA and PsA PBMC and RA and PsA SFMC and plated at a concentration of 1 × 10<sup>5</sup> cells per well in a final volume of 200 μl of culture medium. In some cultures, human recombinant tumour necrosis factor (hrTNF)α, human recombinant interleukin (hrIL)-6 or hrIL-1β (all at 10 ng/ml; R&D Systems) were added in the absence or presence of anti-TNFα drug adalimumab (AbbVie, Chicago, IL, USA), anti-IL-6R drug tocilizumab (Roche, Basel, Switzerland).
Switzerland) or anti-IL-1β mAb (R&D Systems) (all at 1 μg/ml). In some cultures, HC CD4⁺ T cells were cultured in PD-L1Fc (0, 0-1 and 1 μg/ml)-coated plates in the presence of soluble PD-1Fc (0-5 and 1 μg/ml; R&D Systems). In other experiments, freshly isolated HC CD4⁺ T cells and autologous CD14⁺ monocytes (used as a source of PD-L1 ligand) were co-cultured in 96-well flat-bottomed plates (Costar, Corning Inc.) at 1 : 1 ratios (total cells per well 1 × 10⁵) in culture medium containing 100 ng/ml soluble anti-CD3 mAb and soluble PD-1Fc or IgG1Fc (0, 0-25, 0-5 and 1 μg/ml). In all assays, at day 4, cells were pulsed with [³H]-thymidine (0-25 μCi/well) (GE Healthcare, Little Chalfont, UK) and T cell proliferation was assessed after 18 h (on day 5) using a Topcount scintillation counter (Perkin Elmer, Cambridge, UK). Proliferation was determined and expressed as counts per minute (cpm) and as suppression of T cell proliferation (%) according to the following formula: [(medium only condition − PD-L1Fc condition)/medium only condition] × 100.

Detection of soluble cytokines and soluble PD-1

CD4⁺ T cell culture supernatants were collected at day 5 and stored at −80°C. IFN-γ levels were determined by enzyme-linked immunosorbent assay (ELISA) using the ELISA MAX™ standard set (Biolegend). Levels of sPD-1 were determined by human PD-1 DuoSet ELISA (R&D Systems). Serum samples from HC donors and serum and paired cell-free SF samples from patients with OA, RA or PsA were determined by human PD-1 DuoSet ELISA (R&D Systems) or Bio-Plex Pro™ (for TNFα, IL-6 and IL-1β; Bio-Rad Laboratories) on the Luminex FlexMap 3D platform (Luminex Corporation, Austin, TX, USA). All assays were performed according to the manufacturers’ protocols.

RNA extraction and real-time–quantitative polymerase chain reaction (RT–qPCR)

Total RNA was isolated using the ReliaPrep™ RNA cell Miniprep System (Promega, Southampton, UK) according to the manufacturer’s protocol. cDNA synthesis was performed using a high-capacity cDNA reverse transcription kit (Applied Biosystems, Foster City, CA, USA) and mRNA expression of PD-1Δex3 was determined using the SensiMix™ SYBR No-ROX Kit (Bioline, London, UK). Data were collected and analysed on a Rotor-Gene Q thermocycler (Qiagen, Hilden, Germany). The β-actin gene was used as an endogenous control and relative gene expression was expressed as 2−ΔΔCT. PCR primer pairs (IDT, Leuven, Belgium) were as follows: PD-1Δex3, 5’-AGGTTGACAGG GACAATAGG-3’ and 5’-CCATATCCACAGAGAACAC -3’, β-actin, 5’-ATTGGCAATGACGGTTCC-3’ and 5’-CGTGGATGCCAGGACT-3’.

Statistical analysis

Significance testing was performed with GraphPad Prism software (version 7; GraphPad, La Jolla, CA, USA) using the appropriate statistical tests, as indicated in the figure legends.

Results

PD-1⁺ T cell frequencies are increased in RA and PsA synovial fluid compared to peripheral blood

First, we investigated the frequencies of PD-1⁺ cells among T cells in PB and paired SF from patients with RA and PsA. Significantly increased percentages of PD-1⁺ cells were found within SF CD4⁺ T cells (identified either by CD3⁺CD14⁺CD4⁺ cells or CD3⁺CD8⁺ cells) compared to PB (Fig. 1a,b). In addition, increased percentages of PD-1⁺ cells were found within the SF CD8⁺ T cell compartment in both RA and PsA (Fig. 1c,d).

PD-1 ligation reduces proliferation of CD4⁺ T cells from healthy donors, but not CD4⁺ T cells from patients with RA or PsA

To investigate whether the PD-1 expression is functional in RA and PsA, we set up a PD-1 ligation assay using anti-CD3 and PD-L1Fc (or IgG1Fc as control)-coated plates, based on previously described protocols [9,29,30]. As expected, PD-1 ligation resulted in a significant and dose-dependent reduction of healthy control PB-derived CD4⁺ T cell proliferation, while no effect was observed in the presence of IgG1Fc control (Fig. 2a,b). IFN-γ production was also inhibited in a PD-L1Fc dose-dependent fashion (Supporting information, Fig. S1a). We then compared PD-1 ligation of PB-derived CD4⁺ T cells from healthy donors and patients with RA in parallel experiments. In contrast to the suppressive effects on T cell proliferation observed upon PD-1 ligation of CD4⁺ T cells from healthy donors, CD4⁺ T cells from patients with RA appeared to be resistant to PD-1-mediated suppression of T cell proliferation (Fig. 2c,d). Next, we cultured CD4⁺ T cells from the blood and synovial fluid from patients with RA and PsA with increasing doses of plate-bound PD-L1Fc. Even at the highest dose of PD-L1Fc (5 μg/ml) we did not detect a decrease in T cell proliferation upon PD-1 ligation (Fig. 2e,f). Similarly, when RA and PsA cell culture supernatants were tested for IFN-γ production, we could not detect a consistent decrease in the levels of IFN-γ (Supporting information, Fig. S1b). These data indicate that CD4⁺ T cells from the blood and synovial fluid of patients with RA or PsA are resistant to PD-1 ligation compared to healthy control cells.
TNFα, IL-6 and IL-1β counteract PD-1-mediated suppression of CD4+ T cell proliferation

Because RA and PsA CD4+ T cells, especially those from the synovial fluid, are derived from a proinflammatory environment, we sought to examine how inflammatory cytokines may influence PD-1-mediated T cell suppression. First, we determined the levels of TNFα, IL-6 and IL-1β in RA and PsA-derived sera and paired SF, compared to healthy serum and serum and SF from disease control patients with osteoarthritis (OA). Increased levels of all three cytokines were detected in both RA and PsA SF when compared to HC serum or OA SF (Fig. 3a,b). These data confirm the inflammatory nature of SF in both RA and PsA. In the analysed RA and PsA sera, we only found mild increases of TNFα and IL-6 compared to healthy or OA control serum.

Next, we assessed whether the presence of TNFα, IL-6 or IL-1β had a functional impact on PD-1-mediated suppression of CD4+ T cell proliferation. HC CD4+ T cells were cultured with increasing concentrations of PD-L1Fc (0, 0.1 and 1 μg/ml) in the absence or presence of TNFα, IL-6 or IL-1β (10 ng/ml). To block the effect of the cytokines, the anti-TNFα drug adalimumab, anti-IL-6R drug tocilizumab or anti-IL-1β mAb (1 μg/ml) were added at the beginning of the culture where indicated. Addition of each individual cytokine was able to abrogate the suppressive effects of PD-1 ligation on CD4+ T cell proliferation at both 0.1 and 1 μg/ml PD-L1 concentrations (Fig. 3c). In each sample tested, adalimumab, tocilizumab and anti-IL-1β mAb were able to reverse these cytokine-mediated effects completely. Together, these data indicate that the RA- and PsA-associated inflammatory cytokines TNFα, IL-6 and IL-1β can counteract the suppressive effects of PD-1 ligation on CD4+ T cells, at least in vitro.

Soluble PD-1 (sPD-1) is induced in vitro by TNFα and IL-6 in HC CD4+ T cell cultures and can be detected in serum and SF of both RA and PsA patients

Having demonstrated that TNFα, IL-6 and IL-1β can be detected in RA and PsA patients and that each of these...

cytokines abrogates PD-L1fc activity in vitro, we sought to identify a possible underlying mechanism. ELISA analysis of HC CD4+ T cell supernatants from cytokine-stimulated cultures revealed that both TNFα and IL-6 were able to induce sPD-1 compared to medium-only conditions (Fig. 4a,b). No significant increase in sPD-1 was observed in IL-1β-stimulated cultures (Fig. 4c). This increase in sPD-1 was abrogated in the presence of adalimumab or

(e) sPD-1 levels (median with interquartile range) in control disease OA (n = 3–4), RA (n = 5) and PsA (n = 6–7) serum and SF of patients treated with TNFi versus non-TNFi therapy. Data in (a,b,c,e) were analysed by Mann–Whitney test while data in (d) were analysed by Kruskal–Wallis test with Dunn’s multiple comparison test. *P < 0.05, **P < 0.01, ***P < 0.001.
tocilizumab. Quantitative PCR analysis of HC CD4⁺ T cells from the same TNFα- and IL-6-stimulated cultures revealed increases of the PD-1Δex3 splice variant (Supporting information, Fig. S2). These results are in line with a previous study from another group reporting that TNFα promotes sPD-1 expression [31] but also identify IL-6 as an inducer of sPD-1 and PD-1Δex3.

In addition, ELISA analysis revealed that sPD-1 was detectable in none of three OA serum and none of four OA SF samples, while it was detected at high levels in 13 of 17 RA and 13 of 18 PsA serum and SF samples (Fig. 4d). Additionally, cross-sectional analysis of serum and SF from patients with RA or PsA undergoing TNF-inhibitor (TNFi) therapy revealed lower levels of sPD-1 when compared to patients not receiving TNFi therapy (Fig. 4e). These data show that proinflammatory cytokines such as TNFα and IL-6 can modulate the amount of sPD-1.

Moreover, cross-sectional analysis of serum and SF from patients with RA or PsA undergoing TNF-inhibitor (TNFi) therapy revealed lower levels of sPD-1 when compared to patients not receiving TNFi therapy (Fig. 4e). These data show that proinflammatory cytokines such as TNFα and IL-6 can modulate the amount of sPD-1. In vitro studies have shown that sPD-1 can modulate the activity of the ligand in a dose-dependent fashion, resulting in less efficient suppression of T cell proliferation when compared to medium only (Fig. 5a,b). These data indicate that in a CD4⁺ T cell-only culture system, sPD-1 is able to modulate PD-1/PD-L1 interaction.

To test further the ability of sPD-1 to modulate the PD-1/PD-L1 interaction, we set up a co-culture system using HC CD4⁺ T cells and autologous CD14⁺ monocytes. In these experimental conditions, sPD-1fc did not induce any increase in cell proliferation (Supporting information, Fig. S3), suggesting no direct effect on HC CD4⁺ T cells. When cultured with HC CD4⁺ T cells in the presence of increasing amounts of PD-L1fc ligand in the absence or presence of sPD-1fc chimera (0.5 or 1 μg/ml), PD-L1fc precoated plates, addition of sPD-1fc was able to abrogate the activity of the ligand in a dose-dependent fashion, resulting in less efficient suppression of T cell proliferation when compared to medium only (Fig. 5a,b). These data indicate that in a CD4⁺ T cell-only culture system, sPD-1 is able to modulate negatively an otherwise functional PD-1/PD-L1 interaction.

To investigate further the ability of sPD-1 to modulate the PD-1/PD-L1 interaction, we set up a co-culture system using HC CD4⁺ T cells and autologous CD14⁺ cells as a source of natural PD-L1. The ability of HC CD14⁺ cells to express PD-L1 was tested by flow cytometry by culturing the cells overnight with 10 ng/ml of IFN-γ, a known inducer of PD-L1 [27,32] (Supporting information, Fig. S4). Freshly isolated HC CD4⁺ T cells and autologous monocytes were cultured at a 1:1 ratio with soluble anti-CD3 mAb (100 ng/ml) in the absence or presence of increasing doses of sPD-1 or IgG1fc control (0.25, 0.5 and 1 μg/ml). Addition of sPD-1fc led to a significant dose-dependent increase in T cell proliferation compared to control-treated cells (Fig. 5c,d). These data indicate that soluble PD-1 receptor can modulate PD-1 ligation in both an artificial system (PD-L1fc precoated plates) as well as in a more physiological context (in the presence of PD-L1⁺ APC).

Discussion

The present study provides evidence for compromised PD-1 mediated suppression in CD4⁺ T cells from patients with RA and PsA. Our study identifies the proinflammatory cytokines TNFα, IL-6 and IL-1β as negative modulators of PD-1-mediated T cell suppression in vitro and demonstrates that sPD-1 is capable of interfering with effective PD-1 ligation. To our knowledge, this is the first study to examine PD-1 function in RA and PsA simultaneously, and to provide evidence that the inflammatory milieu of these two diseases has a role in modulating PD-1 ligation.

We show that the frequencies of PD-1⁺ T cells within CD4⁺ and CD8⁺ T cell subsets are increased significantly in the synovial fluid from patients with RA or PsA when compared to peripheral blood, thus extending the findings from previous studies focusing only on RA [20,26,27,33]. The increase in the frequencies of PD-1⁺ T cells suggests that in RA and PsA PD-1 might have a role in regulating T cell effectors, especially at the site of inflammation. However, despite this increased frequency of PD-1⁺ T cells, inflammation persists, suggesting that this pathway is impaired in these diseases.

Thus far, only limited data exist regarding PD-1 function in inflammatory arthritis. One study using a PD-L1fc chimera demonstrated that PD-1 ligation inhibited cell proliferation and IFN-γ production by CD4⁺ T cells from peripheral blood of RA patients, but that synovial fluid CD4⁺ T cells required higher concentrations of PD-L1fc to achieve similar levels of inhibition [20]. The authors speculated that the inflammatory milieu found in the RA joint might be accountable for reduced PD-1-mediated suppression, as they showed that addition of cell-free SF to RA PB CD4⁺ T cells modulated PD-1 ligation negatively [20]. However, no specific mediator of the effect was identified. It has been shown previously that the common gamma chain cytokines IL-2, IL-7 and IL-15, as well as CD28 co-stimulation, can interfere with PD-1 cross-linking via pSTAT-5 activation [9,29]. In our study, we show that in both RA and PsA, CD4⁺ T cells from the blood and synovial fluid are more resistant to PD-1 ligation in terms of suppression of T cell proliferation and IFN-γ production when compared to healthy cells. We show that the proinflammatory cytokines TNFα, IL-6 and IL-1β are found at increased levels in RA and PsA SF, and can reduce PD-1-mediated suppression of proliferation in CD4⁺ T cells from healthy donors. Inhibitors of these cytokines can counteract this effect. These findings provide further evidence that the presence of certain proinflammatory
cytokines can be critical in determining the outcome of PD-1 engagement during the immune response.

Mechanistically, our data demonstrate that TNF-α and IL-6, but not IL-1β, induce the secretion of sPD-1 by CD4+ T cells, and that sPD-1 levels are increased significantly in the serum and SF of patients with RA or PsA compared to OA. The latter data support and extend two recent studies that showed that sPD-1 can be detected in the serum and SF from patients with RA [27,34]. In these studies sPD-1 serum levels correlated positively with the Disease Activity Score (DAS28), the presence of rheumatoid factor, and with levels of TNFα in the RA SF but not the serum [27,34]. Recent studies showed that expression of the PD-1Δex3 variant is observed in T cells from patients with RA, but only minimally in T cells from patients with OA or from HC [27,31]. PD-1Δex3 is a splice

Fig. 5. Soluble programmed cell death 1 (sPD-1) modulates PD-1-mediated suppression of healthy control (HC) CD4+ T cells and induces proliferation in CD4+ T cell/CD14+ monocyte co-cultures. (a) Proliferation and (b) suppression of proliferation of HC CD4+ T cells cultured in anti-CD3 monoclonal antibody (mAb) (OKT3) and PD-L1fc pre-coated plates with or without soluble PD-1fc (0.5 and 1 μg/ml) (n = 9–10). (c) Proliferation and (d) suppression of proliferation of HC CD4+ T cells cultured with autologous CD14+ monocytes at a 1:1 ratio (n = 7) in presence of soluble anti-CD3 mAb (100 ng/ml) and soluble PD-1fc/IgG1fc control (0, 0.25, 0.5 and 1 μg/ml). Data were analysed by Friedman’s test with Dunn’s multiple comparison test (a,b) and Wilcoxon’s signed-rank test (c,d). *P < 0.05 and ***P < 0.001.
variant of PD-1, which lacks the transmembrane domain and whose putative translational product is a soluble form of PD-1 [34,35]. It was shown that TNFα, IL-17 and IFN-γ can increase PD-1Δex3 splice variant mRNA expression in healthy human CD4+ T cells [31]. Our data indicate that in addition to those cytokines, sPD-1 protein expression and PD-1Δex3 splice variant mRNA expression can also be regulated by IL-6. Furthermore, preliminary analysis from a cross-sectional investigation of PsA and RA serum and SF suggests that patients treated with TNFi therapy have lower sPD-1 levels compared to patients not treated with TNFi therapy. Further longitudinal studies on patients treated with adalimumab or tocilizumab are required, however, before conclusive statements can be made regarding the effect of biologics on sPD-1 levels.

Our data demonstrate that the inflammatory cytokines TNFα and IL-6 can lead to increased levels of PD-1Δex3 splice variant as well as sPD-1. It is possible that a certain amount of PD-1 might also be released from the cell membrane via other mechanisms. The presence of high levels of certain metalloproteases (MMPs) such as MMP-9 and MMP-13 has been described previously in inflammatory arthritis [36,37], and it has been shown recently that expression of the PD-1 ligands PD-L1 and PD-L2 in infant foreskin fibroblasts can be regulated through proteolytic cleavage by MMPs [38]. Future studies may reveal whether such an MMP-mediated proteolytic cleavage may also contribute to generation of soluble PD-1.

Notably, we show, using a recombinant PD-1 chimera, that sPD-1 is functionally able to counteract PD-L1fc-mediated suppression of healthy CD4+ T cell proliferation, and to enhance CD4+ T cell proliferation when co-cultured with CD14+ monocytes that can naturally express PD-L1. Importantly, recent studies in autoimmune hepatitis [39] and cutaneous systemic sclerosis [40] support the notion that sPD-1 might interfere with the PD-1 pathway, thereby disrupting T cell regulation.

Collectively, our data indicate that CD4+ T cells from the PB and SF of patients with chronic RA or PsA are more resistant to PD-1-mediated regulation than CD4+ T cells from healthy individuals. We show that the proinflammatory cytokines TNFα, IL-6 and IL-1β, which are present at increased levels in the inflamed joints of RA and PsA patients, are capable of negatively modulating PD-1 ligation in vitro. Finally, we show that TNFα and IL-6 are capable of inducing sPD-1 in HC CD4+ T cells and that sPD-1 modulates T cell proliferation by interfering with PD-1 ligation. Thus, our findings provide new evidence that the inflammatory environment of the RA and PsA joint compromises PD-1/PD-L1-mediated T cell regulation.

Acknowledgements

This work was supported by Innovative Medicines Initiative grant BTCure (ref. 115142). The authors would like to thank Professor Bruce Kirkham and Dr Estee Chan from the Department of Rheumatology at Guy’s & St Thomas’ NHS Foundation Trust for their help in collecting patients’ samples. The authors would also like to thank all patients and healthy volunteers who donated blood and synovial fluid for the project. The authors acknowledge financial support from the Department of Health via the National Institute for Health Research (NIHR) comprehensive Biomedical Research Centre award to Guy’s & St Thomas’ NHS Foundation Trust in partnership with King’s College London and King’s College Hospital NHS Foundation Trust.

Disclosure

The authors have declared no disclosures relating to this study.

Author contributions

D. B. conceived the study, performed most of the experiments and wrote the manuscript. C. H. performed some of the experiments. V. M. C. and L. S. T conceived and supervised the study and wrote the manuscript.

Supporting information

Additional Supporting Information may be found in the online version of this article at the publisher’s website.

Supplementary Table 1. Demographic and clinical parameters of the patients included in the study. Some samples were used for flow cytometry or functional assays only, whilst other samples were only used for cytokine detection in serum and SF. Clinical and demographic data are provided, where available. Abbreviations used:
DAS28, disease activity score of 28 joints; DMARDs, disease-modifying anti-rheumatic drugs.

Supplementary Figure 1. PD-1 ligation reduces IFN-γ production by HC CD4+ T cells but not RA or PsA CD4+ T cells. CD4+ T cells from HC PBMC, RA and PsA PBMC and SFMC were cultured in plates pre-coated with anti-CD3 mAb (OKT3) and PD-L1Fc/IgGlFc. Supernatants were collected at day 5 and tested by ELISA for IFN-γ production. (a) IFN-γ production in HC CD4+ T cell cultures in presence of PD-L1Fc (0, 0.1 and 1 μg/ml range; n=11 and 0, 0.1, 1, 2 and 5 μg/ml range; n=4). (b) IFN-γ production in RA and PsA CD4+ T cell cultures; IA PB (RA n=2; PsA n=3) and IA SF (RA n=2; PsA n=4). Data were analysed by Friedman Test with Dunn’s Multiple Comparison test. *P<0.05, **P<0.01 and ***P<0.001.

Supplementary Figure 2. Expression of PD-1Δex3 transcript in activated HC CD4+ T cells in presence of TNFα and IL-6. HC CD4+ T cells were cultured in absence (medium, M) or presence of 10 ng/ml of TNFα (n=4) or IL-6 (n=3) +/- anti-TNFα (adalimumab; ADA) or anti-IL-6R (tocilizumab; TOC) (all at 1 μg/ml) for 5 days. PD-1Δex3 expression was examined by qPCR and normalised to β-Actin housekeeping gene (mean ± SEM).

Supplementary Figure 3. Proliferation of HC CD4+ T cells in presence of increasing sPD-L1c concentrations. HC CD4+ T cells (n=9) were cultured with immobilised anti-CD3 mAb (OKT3) in presence of increasing concentrations of sPD-L1c (0, 0.5 and 1 μg/ml). Proliferation was assessed at day 5 by [3H]-thymidine incorporation and displayed as counts per minute (cpm). Data (mean ± SEM) were analysed by Friedman Test with Dunn’s Multiple Comparison test. *P<0.05, **P<0.01 and ***P<0.001.

Supplementary Figure 4. PD-L1 expression in CD14+ monocytes following IFN-γ stimulation. CD14+ monocytes were positively isolated from HC PBMC and cultured overnight at 37°C in medium only or in medium supplemented with IFN-γ (10 ng/ml). PD-L1 expression was assessed after 12 hrs by flow cytometry. (a) Representative experiment. Shaded histograms represent the isotype control, open histograms indicate the expression profile for PD-L1 with/out IFN-γ stimulation. (b) Cumulative data (n=3).

Supplementary Figure 5. PD 1+ T cell frequencies are increased in synovial fluid compared to peripheral blood. Contour plot of CD3+CD4+PD-1+ cells from paired PBMC and SFMC of one representative RA donor. FMO controls and isotype controls are shown for the CD3+CD4+populations.
