The perceived acceptability of the DEPPA patient assessment tool:
A questionnaire survey of Denplan Excel patients

Abstract

Aim: To establish the perceived acceptability of the use of the Denplan/Previser Patient Assessment tool (DEPPA) by patients. The secondary aim was to examine dental practitioners’ views about the effects of a DEPPA consultation on patients’ future oral health behaviours.

Method: Two questionnaire surveys: 365 patients attending general dental practice, who had been assessed using the DEPPA software; 12 dental practitioners who had completed a DEPPA assessment on the patients. Participants (both patients and GDPs) completed the Treatment Evaluation Inventory (TEI) to ascertain their views of the DEPPA assessment.

Findings: The overall mean for the Treatment Evaluation Instrument for the patients was 23.81 (SD 5.08), and for GDPs 23.81 (SD 2.99).

Conclusion: Participants expressed a high level of expressed acceptability of the DEPPA tool. In particular, the tool is seen as enhancing the relationship between the patient and practitioner and providing information to support behaviour change.
The Denplan/Previser Patient Assessment tool (DEPPA, 1) is an online tool for the assessment of patients in Denplan Excel accredited practices. It seeks to assess the risk of future disease on the basis of risk factors identified from the patient’s medical history, dental history, lifestyle and current clinical condition. DEPPA also produces a score to indicate the patient’s current state of oral health. The programme benefits from extensive empirical validation of its evidence based algorithms (2). The disease risk DEPPA provides is personalised, uses risk scores and can incorporate graphs and as such, is set to communicate disease risk using the best available evidence. A recent review of risk assessment tools for periodontal disease (3) identified that five such instruments exist, and further that risk assessment tools such as DEPPA can be used to predict future deterioration in periodontal health in the absence of treatment. However there is little published literature on the effect of risk communication on patient behaviour, and the acceptability of such measure to patients and dental practitioners.

Risk communication of future disease has a long research tradition (4-7). What is clear is that healthcare professionals and patients alike have difficulties conveying and understanding risk information, especially when such information is communicated in general ways (e.g. “you are at risk for gum disease”) and uses long future time-frames (8,9). It is now accepted that where disease risk communication takes place this information should be tailored to the individual and communicated using simple risk scores and graphs (6).

The effects of risk communication on patients in oral health settings is relatively unexplored with only one recent RCT reporting positive behavioural impacts of individualised risk communication on patients being assessed for periodontal treatment (10); in medicine however, risk communication of future disease has been associated with corrections of patients’ unduly pessimistic views about their risk of future illness and with improvements in patient mood. Risk communication of future disease risk may have an impact on patients’ views of dental treatment. Evaluation of patients’ views of the treatment they have received is a critical component of the introduction of a new service
development. Historically there has been much focus on patient satisfaction with care. Though it has been argued that the concept of ‘satisfaction’ was often used uncritically and without an analysis of the theoretical basis for the construct (11). Furthermore, a review of patient satisfaction studies in dentistry undertaken by Newsome and Wright (12,13) identified that there was a lack of psychometrically sound measures of patient satisfaction with dental services; most studies had developed their own measures of satisfaction while the two most developed scales, the Dental Visit Satisfaction Scale (14) and the Dental Satisfaction Questionnaire (15) each had their own limitations.

The concept of the social validity of dental treatments, based on the work of Wolf (16) suggests that there are three important questions to address in order to determine the social relevance of treatment:

1. Does society deem the program goals to be desirable and appropriate for the client?
2. Are the client and the significant people in their life satisfied with the change that occurred during treatment?
3. Are the procedures used to achieve change acceptable to the client, their significant others and the broader community?

Social validity is perceived to be a broader concept than satisfaction, and aligns with concepts discussed by public health physicians - it is enshrined into the Primary Health Care Approach (17), it is included as a dimension of access (18) and definitions of need (19). Furthermore, treatment acceptability has been shown to be important in ensuring good outcomes. If a treatment is deemed acceptable to patients it is more likely that they will adhere with healthcare professionals’ advice and also show improvements in their condition (20).

Although the patient experience is of paramount importance, it is equally important that with any new service initiative the views of those asked to engage with, adopt and deliver the new service are also sought; it follows that unless dental practitioners see DEPPA as a helpful tool towards patient health
improvement, they are unlikely to use it. At the same time, work in medical settings has shown that physicians’ views of their patients’ health beliefs were grossly inaccurate and differed from patients’ own views (21). It is for this reason that this project seeks to assess dentists’ and patient views about DEPPA separately and where appropriate look for common patterns and areas for further development.

The primary aim of this project therefore was to establish the perceived acceptability of the use of DEPPA by patients. The secondary aim was to examine dental practitioners’ views about the effects of a DEPPA consultation on patients’ future oral health behaviours.

**Method**

**Design**
The study comprised two questionnaire surveys using parallel versions of the Treatment Evaluation Inventory (TEI: 22,23). Dentists participating in the Denplan Excel scheme who have used the DEPPA programme were surveyed, as well as patients following the appointment in which they completed their assessment with DEPPA. The survey method adopted followed guidelines on the design of surveys to maximise response rates (24,25). There was one main mailing and one follow up mailing.

**Participants**

**Dental Practitioners:**

**Inclusion criteria:** Dentists who have undertaken at least 20 DEPPA assessments.

**Exclusion criteria:** Dentists who have not completed 20 DEPPA assessments.

**Patients:**

**Inclusion criteria:** Adult patients undergoing their first DEPPA assessments

**Exclusion criteria:** Insufficient familiarity with written English required to complete the questionnaire
The demographic characteristics of patients attending Denplan Excel dentists are as follows: 43% are male; 17% are aged 35 or younger, 31% are aged over 65. No other information was collected on the age of the patients.

**Procedure**

The study had a two stage recruitment procedure for Dental practitioners. Those dentists (N=158) meeting the entry requirements for the study were sent a letter of invitation and asked to consent to participation, in the second stage those that consented (N=52). The remaining 106 dentists either replied opting out of the research, or did not respond to the initial recruitment approach and were therefore deemed not to consent to participation. The participating dentists were sent copy of the Treatment Evaluation Inventory for practitioners (TEI-Practitioner) for completion. In addition they received 50 copies of the Treatment Evaluation Inventory for patients (TEI-patient) questionnaire to give to patients who completed a DEPPA assessment in their practice over an one-month period. The Dental practitioners were asked to give a copy of the TEI-patient to each patient following completion of the DEPPA assessment. Participants were asked to complete the questionnaire immediately if they choose to and return the questionnaire (completed or uncompleted) to a sealed box at the dentist reception desk before leaving. This sought to ensure that potential participants did not feel under an obligation to complete the questionnaire.

*The Treatment Evaluation Inventory*

The Treatment Evaluation Inventory (22,23) is a commonly used measure of the acceptability of treatments. In this study we used the 6 item form, which has rating scales with anchors of 5 points. Within dentistry this inventory has been used to evaluate interventions for people with dental phobia (26,27); and behavioural management techniques in children (28). Outside the field of dentistry the scale has been used to evaluate interventions for people with mental retardation (29), children and adolescents with behaviour problems (22,23) and youth with eating disorders (30,31). It has been demonstrated to show good internal consistency and criterion related validity in both the full 19
item form and in several short forms including the 6 item form to be used in this study (32,33). Versions are available for patients to rate their treatment, and for practitioners to rate their perceptions of the acceptability of the scale.

Sample size calculation
Previous data on DEPPA activity among Denplan Excel Dentists suggests that there are 158 dentists who would meet the inclusion criteria. Over a one month period these dentists would be anticipated as completing in the region of 2600 DEPPA assessments (Chapple personal communication)

Assuming an overall response rate of 25% this would give a sample size of approximately 39 dentists and 650 patients. These sample sizes will be sufficient to provide a high degree of precision in the estimates of the mean values for the Treatment Evaluation Inventory (+/-4%).

Statistical Methods
The following descriptive statistics were calculated:

- Mean Total TEI scores for Dental Practitioners and Patients
- Item by item analysis of TEI responses for both Dental Practitioners and Patients (34)

Findings

1. Views of Patients
A total of 365 patients returned questionnaires (56.2% of the anticipated sample size). The responses of the patients to the individual TEI items are summarised in Table 2 and Figure 1. The overall mean for the TEI for the patients was 23.81 (SD 5.08).

Table 1 and Figure 1 about here

2. Views of Dental Practitioners
Responses were received from 12 Dental Practitioners – a response rate of 7.6% of eligible dentists, or 23.1% of dentists that consented to participation. Table 1 below shows the distribution of item responses to the Treatment Evaluation Inventory items, given by dental practitioners. The mean overall TEI score for practitioners was 23.81 (SD 2.99). See also Figure 1.

Discussion

This study explored the perceived acceptability of the DEPPA tool among patients and practitioners. Overall the scale was viewed as highly acceptable by both groups. The mean ratings for the overall TEI scores are comparable to the highest ratings of acceptability given for other interventions (see for example 30). For patients the highest scoring items concerned the relationship that they have with the person delivering the DEPPA – there is a perception of a good relationship, and patients also feel that they are able to use the information given to improve their oral health. For both patients and practitioners the item with the least positive responses (though still overall the majority held positive views) was the item relating to increased knowledge. Two possibility exist for the interpretation of this finding: Patients may have good prior knowledge and that information provided during the DEPPA assessment provided no additional benefit, or the DEPPA assessment could be improved by providing an additional element of knowledge provision to support behaviour change. Thus given the risk perception information provided by DEPPA patients may additionally benefit from structured interventions to support behaviour change (10,35).

There are a number of limitations which affect the conclusions that can be drawn from this survey. Data on the demographic characteristics of the participants was not available. In the absence of any demographic characteristics of both patients and practitioners it is impossible to know the degree to which this sample is representative of the general practice population, or indeed those attending Denplan Excel practices, or whether the
practitioners are typical of their colleagues. The response rate was lower than expected which again suggests that it is difficult to infer whether the samples are representative. The smaller than expected sample size also means that the accuracy of the estimates is lower than anticipated.

**Conclusion**

Within the limitations of the study, there is a high level of expressed acceptability of the DEPPA tool. In particular the tool is seen as enhancing the relationship between the patient and practitioner and providing information to support behaviour change.

**Acknowledgements**

Access to Denplan Excel dental practitioners and patients was facilitated by Dr Mike Busby and Dr Elizabeth Chapple of Denplan Limited. Information on the demographic characteristics of patients was provided by Antionette Weller.
