Abstract

We present a method using an extended logical system for obtaining “correct” programs from specifications written in a sublanguage of CASL. By “correct” we mean programs that satisfy their specifications. The technique we use is to extract programs from proofs in formal logic by techniques due to Curry and Howard. The logical calculus, however, has the novel feature that as well as the conventional logical rules it includes structural rules corresponding to the standard ways of modifying specifications: translating (renaming), taking unions of specifications and hiding signatures. Although programs extracted by the Curry-Howard process can be very cumbersome, we use a number of simplifications that ensure that the programs extracted are in a language close to a standard high-level programming language. We use this to produce an executable refinement of a given specification and we then provide a method for producing a program module which respects the original structure of the specification as much as possible. Throughout the paper we demonstrate the technique with a simple example.

1 Introduction

One of the most exciting applications of formal specifications is in the formal development of programs. By gradually refining a high-level specification one eventually obtains a low-level “program” or “executable specification” as in [14], [15]. If each refinement step can be proved correct, then the resulting program is guaranteed to satisfy the original specification. In this paper instead of proving the correctness of a refinement step a posteriori, we show how we can construct refinements from proofs in a way similar to that in which programs are extracted from proofs in mathematical logic (see [3], [6], [2], [11], [1]). As our framework we use a subset of the algebraic specification language CASL [19] that supports structured algebraic specifications with first-order axioms and structuring mechanisms for unions of specifications, translating, and hiding symbols from the signature of a specification. As programs we consider executable specifications where function symbols are specified by means of terms from a simply typed lambda calculus.¹

We choose the simple notion of model inclusion for refinement;² a specification Sp⊥ is a refinement of a specification Sp (written Sp ⊑ Sp⊥) if all models of Sp⊥ (restricted

¹ Research partly supported by ARC grant A 49230989.
² We shall call these “lambda-terms” for brevity.
³ Note that, in combination with the structuring mechanisms, this simple notion of refinement is sufficient for expressing all the interesting notions of refinement of algebraic specifications provided one interprets the equality predicate symbol as a congruence relation instead of the standard equality (see e.g. [17]).
to $\text{sig}(\text{Sp}_\bot)$ are also models of $\text{Sp}$. In the first step we derive a simply typed lambda-term $e$ for each function symbol $f$ of a specification $\text{Sp}$ by extracting lambda-terms from proofs of the axioms of $\text{Sp}$ over another data structure specification, say $\text{Sp}_0$ to obtain $\text{Sp}_\bot$ extending $\text{Sp}_0$ by definitions of the form $f = e$. $\text{Sp}_\bot$ is, by construction, a correct refinement of $\text{Sp}$ and, if $\text{Sp}_0$ is executable, then $\text{Sp}_\bot$ is also executable and we are done. Otherwise we repeat the process.\footnote{Only a finite number of steps will be necessary.}

The new contributions of this paper to the development of specifications are as follows. As far as we know, ours is the first approach (building on our earlier \cite{18}) using program-extraction from (formal) proofs in the area of structured algebraic specifications. Moreover it enhances the program extraction techniques already developed for first-order predicate calculus by methods for dealing with structural rules. A further advantage of our approach is that by the extraction techniques studied in \cite{1}, \cite{11} and \cite{2}, the programs that are automatically extracted are close to those a human developer would have written and the structure of the specification is mirrored in the dependencies of the module extracted. The only similar approach we know of is that of Smith \cite{16} in the SpecWare system. He uses similar techniques to construct specification morphisms. Our technique differs from his in the specification-building operations and in the program-extraction technique.

The paper is organized as follows: In § 2, we introduce the specification language and introduce our example, which is developed throughout the paper. § 3 gives the background from mathematical logic, presenting a sound and complete proof-system for properties of structured specifications in constructive first-order logic. § 4 studies Curry-Howard reductions and strong normalization, and we present our method of program extraction and the transformation of the extracted programs to a "human-readable" form.

## 2 Structured specifications

In writing large specifications it is convenient to design specifications in a structural and modular fashion by combining and modifying smaller specifications. This helps us to master the complexity arising from a large number of function symbols and axioms.

We employ three specification-building operations from CASL \cite{19}. A basic specification is of the form $\langle \Sigma, Ax \rangle$, where $\Sigma$ is a signature consisting of a set of sorts (i.e. names for carrier sets), a set $F$ of $S^* \rightarrow S$-sorted function symbols and a set $P$ of $S^* \times S$-sorted predicate symbols. $Ax$ is a set of $\Sigma$-formulae. Each such formula is a Harrop formula (see § 4) sometimes of the form $f(x_1, \ldots, x_n) = e$ where $e$ is a $\lambda$-expression. (For the final syntax see § 4.)

The specification-building operations for constructing specifications from basic ones are: translation, union and hiding.\footnote{In \cite{18} we used SPECTRUM instead of CASL, building the sum of two specifications instead of union and export instead of hiding and we wrote $1. p \bullet \text{Sp}$ for the translation of $\text{Sp}$ by $p$, where $p$ is a symbol mapping, 2. $\text{Sp}_\bot + \text{Sp}_2$ for the sum of the two specifications and 3. $\text{Sp}_\bot \{x\}$ for hiding the symbols in $\Sigma$ from the signature, where $\Sigma$ is a symbol list.}

As the concrete syntax for our examples we use a subset of the specification language that admits all the above constructs together with the syntax of simply typed lambda-calculus.\footnote{In our language we do not treat subsets and we assume that all functions are total.}
Logical Rules

Introduction Rules
\[
\{x : A\} \vdash_{\text{sig}(A, v)} as(A, x) : A \quad (\text{Ass I})
\]
\[
\emptyset \vdash_{\Sigma, A} ax((\Sigma, Ax), x) : A \quad (\text{Ax I})
\]
\[
\Gamma \cup \{x : A\} \vdash_{\text{Sp}} d : B \quad (\rightarrow I)
\]
\[
\Gamma \vdash_{\text{Sp}} \lambda x : A.d : (A \rightarrow B) \quad (\forall I)
\]
\[
\Gamma \vdash_{\text{Sp}} d : A \quad V_1 \quad \Gamma \vdash_{\text{Sp}} \langle \pi_1, d \rangle : (A \land B) \quad (\land I)
\]
\[
\Gamma \vdash_{\text{Sp}} e : B \quad V_2 \quad \Gamma \vdash_{\text{Sp}} \langle \pi_2, e \rangle : A \land B \quad (\lor I)
\]
\[
\Gamma \vdash_{\text{Sp}} d : A[t/x] \quad (\exists I)
\]
\[
\text{if } x \notin f_0(B) \text{ for every } b : B \in \Gamma
\]
where \(x\) is of sort \(s\)

Elimination Rules
\[
\begin{align*}
\Gamma \vdash_{\text{Sp}} d : (A \rightarrow B) \quad & \quad \Gamma_1 \vdash_{\text{Sp-1}} e_1 : A \quad \Gamma_2 \vdash_{\text{Sp-2}} e_2 : B \quad (\rightarrow E) \\
\Gamma \vdash_{\text{Sp}} d : A_1 \land A_2 \quad & \quad \Gamma \vdash_{\text{Sp}} \pi_1(d) : A_i \quad (\land E)
\end{align*}
\]
\[
\begin{align*}
\Gamma \vdash_{\text{Sp}} d : \forall x : s \cdot A \quad & \quad \Gamma \vdash_{\text{Sp}} d[t/x] : B \quad (\forall E) \\
\Gamma_1 \cup \{x : A\} \vdash_{\text{Sp-1}} d : C \quad \Gamma_2 \cup \{y : B\} \vdash_{\text{Sp-2}} e : C \\
\Gamma \vdash_{\text{Sp}} \langle \{d, e\} \rangle : (A \lor B) \quad & \quad \Gamma^* \vdash_{\text{Sp}*} \text{case}(x : A, d : C, y : B, e : C, f : (A \lor B)) : C \quad (\lor E)
\end{align*}
\]

where \(\Gamma^* = (\Gamma_1 \cup \Gamma_2 \cup \Gamma) \cup \{x : A\} \cup \{y : B\} \) and \(\text{Sp}^* = \text{Sp-1} \land \text{Sp-2} \land \text{Sp}\)

\[
\begin{align*}
\Gamma \vdash_{\text{Sp}} d : A \quad & \quad \rho(\Gamma) \vdash_{\text{Sp}} \rho \cdot d : \rho(\Gamma) \quad (\text{ren}) \\
\Gamma \vdash_{\text{Sp}} d : A \quad & \quad \Gamma \vdash_{\text{Sp}} \text{hide } z \vdash_{\text{Sp}} \text{hide } \Sigma : A \quad (\text{hide})
\end{align*}
\]
\[
\begin{align*}
\text{if } \Gamma \text{ is a } \text{sig}(\text{Sp} - \Sigma)\text{-context} \\
\text{and } A \text{ is a } \text{sig}(\text{Sp} - \Sigma)\text{-formula}
\end{align*}
\]
\[
\begin{align*}
\Gamma \vdash_{\text{Sp}} d : A \quad & \quad \Gamma \vdash_{\text{Sp}} \text{union}_1(d, A) : A \quad (\text{union}_1) \\
\Gamma \vdash_{\text{Sp}} d : A \quad & \quad \Gamma \vdash_{\text{Sp}} \text{union}_2(d, A) : A \quad (\text{union}_2)
\end{align*}
\]

Fig. 1. Logical and Structural Rules
below), but we restrict the other axioms to be Harrop formulae.⁶
In CASL translation is written \( \text{Sp} \) with \( \rho \), where \( \rho \) is a symbol mapping,

\[
\text{union is written} \quad \text{Sp}_1 \quad \text{and Sp}_2
\]

and hiding is written \( \text{Sp} \) hide \( \Sigma \), where \( \Sigma \) is a symbol list.

Note that many of the other common specification operators (extension, revealing, and
local specifications) used in CASL can be constructed from these three operators.

Example. We use the following example throughout the paper to illustrate our method
of program extraction from a structured specification. Consider the three specifications
\( \text{Nat}_A \), \( \text{Nat}_B \) and \( \text{Nat}_C \) in Fig 3. (We shall eventually show how we can obtain
a program for \( c \) in \( \text{Nat}_C \).) First we unSkolemize (see Theorem 3, § 3) the axiom for \( c \):
\( \exists y : \text{Nat} \bullet y \geq s(s(s(0))) \). We prove this formula constructively, using the other two
specifications (\( \text{Nat}_A \) and \( \text{Nat}_B \)), and then extract a program for \( y \) which computes
\( c \). From this, we can produce an executable specification, and also a program module
corresponding to it, which is a refinement of \( \text{Nat}_C \).

3 The formal calculus

We extend the Curry-Howard terms, or proof-terms, for a logical calculus for structured
algebraic specifications based on classical logic, introduced in[18], to one based on
constructive logic.⁸⁹ There are two reasons for doing this. First we can extract programs
directly from the proof-terms, and secondly it allows us to make further extensions which
we describe in § 4.

We use the syntax of CASL with logical connectives¹⁰ \( \bot \) (false), \( \land \), \( \lor \), \( \to \) and \( \exists \). The system uses sequents of the form \( \Gamma \vdash \text{Sp} \ D : A \) where \( \Gamma \) is a context, \( \text{Sp} \) is a specification,¹¹
and \( D \) is a proof-term that gives a precise representation (see remark 5, below) of the
derivation of \( A \) from the assumptions from \( \Gamma \) in the environment of the specification \( \text{Sp} \).
From a type-theoretic point of view \( A \) is the type¹² of \( D \). Recall that the axioms in \( \text{Sp} \) may
be used in addition to those from \( \Gamma \) to prove the formula \( A \) whose signature is (contained in)
\( \text{Sp} \). As in [18] we have a set of rules. We present these in natural deduction style (see
[7] or [18]). The rules for the basic system are of two kinds, logical and structural,¹³ see
Fig 1.

⁶ For the definition of Harrop formulae and a discussion of their rôle see § 4. The restriction is not significant
in practice and in particular is no restriction at all in the case of algebraic specifications with purely universal
axioms.

⁷ In particular, we use the extension “\( \text{Sp} \) then \( \Sigma \), \( A \)” as shorthand notation for “\( \text{Sp} \) and \( \langle \text{sig}(\text{Sp}) \cup \Sigma, A \rangle \)”.

⁸ Constructive (or Intuitionistic) logic is not commonly used in formal mathematical proofs, but in fact most
proofs used in Computer Science to produce programs are either constructive or can easily be made so.

⁹ Indeed, for proofs of formulae of the form \( \forall x : s; \exists y : s' \bullet A(x, y) \), where \( A \) is quantifier-free, and contains
no free variables other than \( x \) and \( y \), any classical proof can be transformed into a constructive one (see Kleene
[13] or Schwichtenberg [3]).

¹⁰ We need all of these connectives because e.g. the De Morgan laws \( \neg(A \land B) \leftrightarrow (\neg A \lor \neg B) \) do not hold in
general in constructive logic. Negation, \( \neg A \), is an abbreviation for \( (A \to \bot) \), and \( (A \leftrightarrow B) \) is regarded as an
abbreviation for \( ((A \to B) \land (B \to A)) \).

¹¹ Again, as in [18], \( \text{Sp} \) is considered as an equivalence class \text{modulo} a simple decidable equivalence relation on
specifications. (See [18], §2 for more details.)

¹² This type will therefore be non-empty when \( A \) has a proof.

¹³ Remarks on the rules. 1. For the rules \( (\forall I) \), \( B \) must be a \( \text{sig}(\text{Sp}) \)-formula in \( (\forall I) \) and \( A \) must be a
\( \text{sig}(\text{Sp}) \)-formula in \( (\forall I) \).

2. As usual \( A[t/x] \) denotes the result of substituting \( t \) for all free occurrences of \( x \) in \( A \) subject to avoiding
cashes of variables; and, in the rules \( (\forall E) \) and \( (\exists E) \), the individual variable \( z \) must not be free in \( C \) nor in any
uncancelled premise.

3. The rule \( (\forall E) \) is most easily understood by its analogy to proof by cases. If we have a proof of \( C \) from \( A \)
\[ \text{spec } \text{NAT}_0 = \]
\[ \text{sorts} \]
\[ \text{Nat} \]
\[ \text{ops } \theta : \text{Nat}; \ s : \text{Nat} \to \text{Nat}; + : \text{Nat} \times \text{Nat} \to \text{Nat} \]
\[ \text{preds} \]
\[ \geq : \text{Nat} \times \text{Nat} \]
\[ \text{axioms} \]
\[ \text{NAT}_0.1 : \forall x : \text{Nat} \bullet x + 0 = x \]
\[ \text{NAT}_0.2 : \forall x : \text{Nat} ; \forall y : \text{Nat} \bullet x + s(y) = s(x + y) \]
\[ \text{NAT}_0.3 : \forall x : \text{Nat} ; \forall y : \text{Nat} \bullet x \geq 0 \]
\[ \text{NAT}_0.4 : \forall x : \text{Nat} ; \forall y : \text{Nat} \bullet x + y = y + x \]
\[ \text{NAT}_0.5 : \forall x : \text{Nat} ; \forall s(x) \geq x \]
\[ \text{NAT}_0.6 : \forall x : \text{Nat} , \forall y : \text{Nat} ; \forall z : \text{Nat} ; \forall w : \text{Nat} \bullet x \geq y \geq w \to x + y \geq v + w \]

\[ \text{end} \]

\[ \text{spec } \text{NAT}_A = \]
\[ \text{spec } \text{NAT}_B = \]
\[ \text{spec } \text{NAT}_C = \]
\[ \text{Nat} \]
\[ \text{Nat} \]
\[ \text{Nat} \]
\[ \text{ops } a : \text{Nat} \]
\[ \text{ops } b : \text{Nat} \]
\[ \text{ops } c : \text{Nat} \]
\[ \text{axioms} \]
\[ \text{axioms} \]
\[ \text{axioms} \]
\[ A : a \geq s(s(0)) \]
\[ B : b \geq s(0) \]
\[ C : c \geq s(s(s(0))) \]

\[ \text{end} \]

\[ \text{end} \]

\[ \text{end} \]

\[ \text{fig. 2. Specifications } \text{NAT}_A, \text{NAT}_B \text{ and } \text{NAT}_C. \]

The logical rules are standard for a constructive system.\(^\text{14}\) There are two kinds of logical rules: introduction rules and elimination rules. With the logical rules, the specification of the conclusion includes those of the premises while, for the structural rules, the change in the structure is reflected in the specification of the conclusion.\(^\text{15}\)

**Theorem 1 (Soundness and completeness).** The above system of logical and structural rules is sound and complete.

The proof of completeness\(^\text{16}\) proceeds as in Cengarle [5]. We use the flat (basic) normal form theorem as in [18], §2, the interpolation and compactness theorems for first-order constructive logic.

In addition to logical axioms and the axioms in the specification, we also have some implicit axioms that must be made explicit in our logical system. First the usual axioms for equality are assumed (i.e. reflexivity, symmetry, transitivity and substitutivity in both functions and predicates). Secondly, if a specification predicate is decidable, then we have the law of double negation for such predicates including equality at the base level,\(^\text{17}\) e.g. \(\forall x : s \bullet \forall y : s \bullet (\neg \neg x = y \to x = y)\) and we note that this is a Harrop formula (see §4).

We are now ready to prove the unSkolemized axiom for \(c\)

\[ \vdash \text{NAT}_C \exists y : \text{Nat} \bullet y \geq s(s(s(0))) \] \hfill (1)

and also a proof of \(C\) from \(B\) then we get a proof of \(C\) from \(A \lor B\).

4. Likewise in (3 B), if we have a proof of \(\exists x : s \bullet A\) and a proof of \(C\) from a proof of \(A\) with free variable \(y\), then we can get a proof of \(C\).

5. As in [18]: 3, we assume that there are functions \(\text{for}(d)\), \(\text{sp}(d)\) and \(\text{con}(d)\) from proof-terms to formulae, specifications and contexts, respectively, such that \(\text{for}(d)\) is the formula proved, \(\text{sp}(d) = \text{Sp}\) and \(\text{con}(d)\) is the current context. We call \(\text{sp}(d)\) the associated specification of \(d\).

\(^{14}\)We use slight variants of the ones found in [7], but these can readily be replaced by those of any other natural deduction system.

\(^{15}\)A proof is, as usual, a tree whose leaves are axioms or assumptions and where succeeding nodes are obtained by the rules.

\(^{16}\)This logic is constructive. The same result also holds for classical logic when the law of double negation is added.

\(^{17}\)Higher order equality may be a defined predicate. In such a case it may be necessary to prove the equality axioms at this higher-order level within the system.
using our calculi. We may use the axioms from NAT C that do not involve c.
We start with the NAT A and NAT B axioms:

\[ \vdash_{\text{NAT A}} ax(\text{NAT A}, A) : a \geq s(s(0)) \quad \text{and} \quad \vdash_{\text{NAT B}} ax(\text{NAT B}, B) : b \geq s(0) \]  

(2)

Then, by (\&-I) on the two formulae in (2), setting \( q \equiv (ax(\text{NAT A}, A), ax(\text{NAT B}, B)) \):

\[ \vdash_{\text{NAT A and NAT B}} q : a \geq s(s(0)) \land b \geq s(0) \]  

(3)

Now, we have the following axiom from NAT D:

\[ \vdash_{\text{NAT D}} ax(\text{NAT D}, \text{NAT D} 0 6) : \forall x : \text{Nat} ; \forall y : \text{Nat} ; \forall v : \text{Nat} ; \forall w : \text{Nat} \cdot x \geq v \land y \geq w \rightarrow x + y \geq v + w \]

Since NAT C is built from NAT D we have the proof-term

\[ \vdash_{\text{NAT C}} d : \forall x : \text{Nat} ; \forall y : \text{Nat} ; \forall v : \text{Nat} ; \forall w : \text{Nat} \cdot x \geq v \land y \geq w \rightarrow x + y \geq v + w \]

where \( d = \text{union}_2(ax(\text{NAT D}, \text{NAT D} 0 6), \langle \text{sig}(\text{NAT D} \cup \{ c \}), C : c \geq s(s(0))) \rangle) \). If we perform the structural rule (\text{union}_2) twice on this axiom with respect to the specifications NAT A and NAT B, then we shall have:

\[ \vdash_{\text{NAT A and NAT B and NAT C}} \text{union}_2(d, \text{NAT B}, \text{NAT C}) : \forall x : \text{Nat} ; \forall y : \text{Nat} ; \forall v : \text{Nat} ; \forall w : \text{Nat} \cdot x \geq v \land y \geq w \rightarrow x + y \geq v + w \]

\[ \vdash_{\text{NAT A and NAT B and NAT C}} \text{union}_2(ax(\text{NAT C}, \text{NAT D} 0 6), \text{NAT B}, \text{NAT C}))a : \forall y : \text{Nat} ; \forall v : \text{Nat} ; \forall w : \text{Nat} \cdot a \geq v \land y \geq w \rightarrow a + y \geq v + w \]

Next we apply \( \forall \)-E three more times, substituting \( b \) for \( y \), \( s(s(0)) \) for \( v \) and \( s(0) \) for \( w \). This gives:

\[ \vdash_{\text{NAT A and NAT B and NAT C}} r : a \geq s(s(0)) \land b \geq s(0) \rightarrow a + b \geq s(s(0)) + s(0) \]  

(4)

where \( r = (((\text{union}_2(ax(\text{NAT C}, \text{NAT D} 0 6), \text{NAT B}, \text{NAT C}))a)b)s(s(0)))s(0) \).

Applying (\( \rightarrow \)-E) to (3) and (4), and setting \( k \equiv rq \) gives:

\[ \vdash_{\text{NAT A and NAT B and NAT C}} k : a + b \geq s(s(0)) + s(0) \]  

(5)

By the substitutivity of equality over predicates and the \( + \)-axioms in NAT C, we obtain

\[ \vdash_{\text{NAT A and NAT B and NAT C}} k' : a + b \geq s(s(0)) \]  

(6)

for some term\(^{19}\) \( k' \). Then we apply (\( \exists \)-I) to (5) with \( y \) as witness for \( a + b \) to give

\[ \vdash_{\text{NAT A and NAT B and NAT C}} (a + b, k') : \exists y : \text{Nat} \cdot y \geq s(s(0)) \]  

(7)

Finally, we wish to prove equation (1) \( \exists y : \text{Nat} \cdot y \geq s(s(0))) \) for the specification NAT C, and hide the symbols \( a, b \) from the signatures of NAT A and NAT B, we obtain (setting NAT C \_1 = (NAT A and NAT B and NAT C) hide \( a, b \)):

\[ \vdash_{\text{NAT C \_1}} (a + b, k') \text{ hide } a, b : \exists y : \text{Nat} \cdot y \geq s(s(0)) \]  

(8)

This is the unSkolemized version of the axiom for \( c \) in NAT C, as required. Later we shall show how to extract a program for \( c \) from this Curry-Howard term.

\(^{18}\) Note that we do not need brackets in NAT A and NAT B and NAT C because of footnote 11 above.

\(^{19}\) Although \( k' \) is initially complicated because of the logical steps required, nevertheless it rapidly reduces as in §4 below because the formulae involved are Harrop.
4 Extracting Programs from Proofs

There is a well-known map from constructive proof-terms to terms in a simply typed lambda calculus with product types which yields programs.\(^{20}\) We call the [terms of] this calculus \(A\). We now describe the analogous map for proof-terms extended with structural symbols.

The proof of strong normalization (see [18]) for such a lambda calculus shows us how to obtain (programs for) new functions from proof-terms for theorems of the form \(\forall x : s; \exists y : s' \bullet A(x, y)\). Each proof-term can be thought of as a program (in a lambda calculus with dependent sum and product types). Thus, proof normalization, proof-term reduction and program evaluation may be considered as equivalent notions. A similar (naive) method of program extraction might be used for our proof-terms.

So, in this sense, the proof-term \((a + b, k')\) of

\[ \vdash \text{Nat}_a \quad \text{and} \quad \text{Nat}_b \quad \text{and} \quad \text{Nat}_c \quad (a + b, k') : \exists y : \text{Nat} \bullet y \geq s(s(s(0)))) \quad (7) \]

can be thought of as a program. Unfortunately, such a direct method of program extraction yields awkward programs. There are two reasons for this: one concerns Harrop formulae, and the other the use of (hide).

**Harrop Formulae and their Associated Reductions.** First we note how systematic treatment of Harrop\(^{21}\) formulae enables us to extract more realistic programs. Intuitively these formulae contain no essential use of \(\exists\) or \(\lor\). This means that the (sub-)terms that we associate with Harrop formulae have no “computational content” and therefore can be “deleted” from the program. Algebraic specifications will very often have Harrop formulae for their axioms.

**Definition 1.** A formula is a Harrop formula if it is 1. an atomic formula, 2. of the form \((A \land B)\) where \(A, B\) are Harrop, 3. of the form \((Z \rightarrow A)\) where \(A\) (but not necessarily \(Z\)) is Harrop or 4. of the form \(\forall x : s \bullet A\) where \(A\) is Harrop.

**Reduction Rules** for proof-terms for Harrop formulae are very simple (see the appendix).

**Logical Reductions.** In addition to the proof-term reductions to be found in [18] we have some additional ones. Some arise from the new logical reductions for the additional connectives \(\lor\) and \(\exists\), and some from structural reductions. These are given below (but for full details see [7]).\(^{22}\) Here is the reduction\(^{23}\)

\[
\frac{\Gamma \vdash \{x : A\} \vdash \text{Sp} \bot \quad d : C}{\Gamma \vdash \text{Sp} \bot \quad \text{and} \quad \text{Sp} \quad \text{case}(x : A, d : C, y : B, e : C, s, \langle \pi, g \rangle : (A \lor B)) : C} \quad (\lor 1 - I) \\
\frac{\Gamma \vdash \text{Sp} \bot \quad \text{and} \quad \text{Sp} \quad \text{case}(x : A, d : C, y : B, e : C, s, \langle \pi, g \rangle : (A \lor B)) : C}{\Gamma \vdash \text{Sp}(\pi, g)(A \lor B) \quad (\lor E)}
\]

\(^{20}\) In fact these can readily be transformed into programs in the usual programming languages (such as C++, ML, etc.).

\(^{21}\) Harrop formulae are named for Ronald Harrop (see his [10]).

\(^{22}\) The substitution that we need is as in [18] supplemented by substitution of the extra terms we have because of the additional logical rules. However, if we use the implementation of the reductions given in [7] for case and select, then we do not need any extra clauses.

\(^{23}\) We have assumed that the specification and contexts for the two proofs of \(C\) are the same. It would be possible to admit different specifications and contexts but then there would need to be some adjustment in the reduction to ensure that the conclusion of the reduced proof had the same specification and context as the original. For \((\lor 1, I)\) immediately followed by \((\lor 1, E)\). This is because the conclusion may be used in a later inference.
This sequence of logical rules then reduces to

\[
\begin{align*}
\vdash \Gamma, \bar{\{x : A\}} & \vdash_{\text{Sp}} d : C \quad \Gamma \vdash_{\text{Sp}} g : A \\
\Gamma \cup \Gamma & \vdash_{\text{Sp}} \text{case}(x : A, d : C, y : B, e : C, \langle \pi_1, g\rangle : (A \lor B)) : C \quad \vdash (\Gamma_1 \cup \Gamma) \vdash_{\text{Sp}} \text{case}(x : A, d : C, y : B, e : C, \langle \pi_1, g\rangle : (A \lor B)) : C \\
& \vdash_{\text{Sp}} \text{case}(x : A, d : C, y : B, e : C, \langle \pi_1, g\rangle : (A \lor B)) : C
\end{align*}
\]  

(\text{Ass-E})

Denoting “reduces to” by \(\succ\), the corresponding proof-term reduction is:24

\[
\vdash_{\text{Sp}} \text{case}(x : A, d : C, y : B, e : C, \langle \pi_1, g\rangle : (A \lor B)) : C \succ (\Gamma_1 \cup \Gamma) \vdash_{\text{Sp}} \text{case}(x : A, d : C, y : B, e : C, \langle \pi_1, g\rangle : (A \lor B)) : C
\]

Any sequence of such reductions always terminates, that is to say, we have strong normalization. The proof is like that in [18] using techniques from [7] and Girard [9].

Extracting Programs from Modular Proofs. When we define our function \text{extract} giving programs from certain proof-terms, we must be careful of the use of \text{(hide)}. For instance, the proof-term in formula (8) is obtained after applying (hide) to \(a\) and \(b\):

\[
\vdash \text{NAT.C.L} (a + b, k') \text{ hide } a, b : \exists y : \text{Nat} \cdot y \geq s(s(s(0)))
\]

If we were to extract the program for this term using the extraction map as it is defined, ignoring the applications of \text{(hide)}, we would obtain the illegal term \(a + b\) which contains the hidden symbols \(a\) and \(b\).25 To avoid this we insist the proof-term be modular according to definition 2 below.26 We say that a Curry-Howard term \(e\) depends on a symbol \(t\) if the proof associated with \(e\) contains the symbol \(t\).

Definition 2. A proof-term \(d\) is said to be critical with respect to a symbol list \(\Sigma\) if

1. \(d\) is of the form \text{hide} \ \Sigma and
2. if the term \(e\) depends on symbols that are in \(\Sigma\): \(\text{sig}(\text{sp}(e)) \cap \Sigma \neq \emptyset\).

A proof-term is said to modular if it contains no critical (sub-)proof-terms.

Lemma 1 (Extraction). There is a “forgetful” map \text{extract} from proof-terms to terms in \(\text{A}\), such that, given any proof \(\vdash_{\text{Sp}} d : A\), with the term \(d\) being modular, then \text{extract}(d) is in \(\text{A}\), is well typed and is an extended realizer (see [3] and below) for \(A\).

\text{extract}(p) removes “non-computational” type information from \(p\) to extract a simple type. The definition of \text{extract} is given in the appendix and is the same as in [2] or [3], modulo the hiding, translating and union operators and the algorithms we have given above in §4 which are used in an extraction map for getting programs from proof-terms.27 For the example above in (7) without \text{hide}, we have \text{extract}((a + b, k')) = a + b.

For the moment we consider a CASL syntax extended with product and disjoint union types in the range of functions simply for the convenience of presenting our results easily.

24 Notice that the interaction is principally between the proof-terms \(\langle \pi_1, g\rangle\) and \(d\).

25 Later, we shall in fact produce an executable specification by adding a definition for \(c\) as the [output of the] program extracted from this proof. For this we shall require that the program extracted contain references only to the visible symbols in its associated specification.

26 Note that definition 2 below is, in fact, an inductive one associated with the definition of a proof.

27 The reader is referred to our appendix and ([2] and [3]) for details, including how the specification is computed. These algorithms can be extended to an extraction map which extends the usual algorithm by replacing occurrences of \(p \otimes t\) by the application of \(p\) to \(t\) (written \(\rho(t)\)) and replacing terms of the form \(\text{union}(a, Sp)\) by \(a\) prior to “deleting”.
First recall that the Skolemization of a constructively proved \( \forall \exists \) formula \( \forall x : s, \exists y : s \cdot P(x, y) \) gives a formula, equivalent with respect to satisfaction, \( \forall x : s \cdot P(x, f(x)) \). This Skolemized formula is true for a certain function \( f \).

In order to define our extraction procedure we need the \textit{extended Skolemization} of any constructively provable formula \( A \). That is to say, given a constructively proved formula \( A \), we build an equivalent Harrop formula \( P(f_A) \) which will be true for a certain function \( f_A \).

**Definition 3 (Extended Skolemization).** Given a closed formula \( A \), we define the extended Skolemization of \( A \) to be the Harrop formula \( Sk(A) = Sk'(A, \emptyset) \), where \( Sk'(A, AV) \) is defined as follows. A unique function letter \( f_A \) is associated with each such formula \( A \) (see clause 6.). \( AV \) represents a list of application variables in \( A \). (That is to say, the variables which will be the arguments of \( f_A \).) If \( AV = \{ x_1 : s_1, \ldots, x_n : s_n \} \) then \( f(AV) \) stands for the function application \( f(x_1, \ldots, x_n). \)

1. If \( A \) is Harrop, then \( Sk'(A, AV) \equiv A \)
2. If \( A \equiv B \lor C \), then \( Sk'(A, AV) \equiv \pi_1 f_A(AV) = \pi_1 \rightarrow (Sk'(B, AV)[\pi_2 f_A/f_B]) \land \pi_1 f_A(AV) = \pi_2 \rightarrow (Sk'(C, AV)[\pi_2 f_A/f_C]) \).
3. If \( A \equiv B \land C \), then \( Sk'(A, AV) \equiv Sk'(B, AV)[\pi_1 f_A/f_B] \land Sk'(C, AV)[\pi_2 f_A/f_C] \).
4. If \( A \equiv B \Rightarrow C \), then \( Sk'(A, AV) \equiv Sk'(B, AV) \Rightarrow Sk'(C, AV \cup \{ f_B \})[f_A/f_C] \).
5. If \( A \equiv \forall x : s \cdot B \), then \( Sk'(A, AV) \equiv \forall x : s \cdot Sk'(B, AV \cup \{ x : s \})[f_A/f_B] \).
6. If \( A \equiv \exists y : s \cdot B \), then \( Sk'(A, AV) \equiv Sk'(B, AV)[f_A(AV)/y : s] \).

So, for example, given a formula \( A \equiv \exists y \cdot y \geq s(s(s(0))) \) we have \( Sk(A) \equiv f_A \geq s(s(s(0)))) \).

**Definition 4 (Extended Realizer).** Given a formula \( A \), \( f_A \) is an extended realizer of \( A \) if, and only if, \( Sk(A) \) is provable.

So for the example above, if we can prove \( f_A \geq s(s(s(0)))) \), then \( f_A \) is an extended realizer of \( A \). When we extract a program for a proof of \( \vdash_{Sp} d : A \), we produce an extended realizer for \( A \). In particular, if we define \( f_A = \text{extract}(a + b, k') \) we obtain an extended realizer for our example. We also have

**Lemma 2.** If \( \vdash A \) then there is an extended realizer \( f_A \) such that \( \vdash Sk(A) \) and conversely.

The next theorem shows that when we extract a term \( \text{extract}(d) \) in \( A \) from a proof \( \vdash_{Sp} d : A \), the equality \( f_A = \text{extract}(d) \) and the formula \( Sk(A) \) can be added to \( Sp \) as axioms, and \( f_A \) can be added to \( \text{sig}(Sp) \). This will give a larger specification which is a correct refinement of \( Sp \).

**Theorem 2.**\(^{28}\) Given a proof \( \emptyset \vdash_{Sp} d : A \) such that \( d \) is modular, \( e = \text{extract}(d) \) and \( \overline{d} \) (of types \( T_1, \ldots, T_n \), respectively) is the list of all free variables in \( e \), let \( f_A \) be as given by definition 4 and define \( \text{NewSpec}(Sp, A, e) = \text{NEW} \), say, by

\[
\begin{array}{l}
\text{spec} \quad \text{NEW} = \\
\quad \{
\quad \text{Sp} \quad \text{then}
\end{array}
\]

\(^{28}\) Note that for CASL specifications this theorem will hold only if \( A \) is a Harrop formula or does not contain non-Harrop subformulae of the form \( B \Rightarrow C \). Otherwise, \( f_A \) will have a higher order type and other new operators \( f_B \) will be included in the signatures.
ops \( f_A : T \rightarrow s \)
axioms \( \forall \overrightarrow{x} \cdot f_A(\overrightarrow{x}) = e(\overrightarrow{x}) \)
Sk(A) 
end
where \( T = T_1 \times \ldots \times T_n \). Then \( \text{NewSpec}(\text{Sp}, A, e) \) is a correct refinement of \( \text{Sp} \).

Proof. Since \( e \) is an extended realizer of \( A \), it follows that \( \text{Sk}(A) \) is true when \( f_A(x) = e(x) \).

**Definition 5.** We define an additional constructor \texttt{unextract} for proof-terms. Given a extended realizer \( e \) of \( A \) in \( \text{Sp} \) then we add \( \vdash_{\text{Sp}} \texttt{unextract}(e, \text{Sp}) : A \) to our logical calculus and define \( \text{sp} \texttt{(unextract}(e, \text{Sp})) = \text{Sp} \).

\texttt{unextract} is needed for eliminating critical subterms from proofs by extracting intermediate programs from subproofs.

If the proof-term \( d \) is modular, then we can use theorem 2 to give us the following rule as a conservative extension to our calculus.

\[
\varnothing \vdash_{\text{Sp}} \texttt{unextract}(f_A, \text{NewSpec}(\text{Sp}, A, \text{extract}(d))) : A \quad (\text{Sk})
\]

The resulting specification \( \text{NewSpec}(\text{Sp}, A, \text{extract}(d)) \) is a conservative extension of \( \text{Sp} \) since if \( \text{NewSpec}(\text{Sp}, A, \text{extract}(d)) \) is inconsistent, then, by Theorem 6.20 of [7], so too is \( \text{Sp} \).

In the same way in addition to functions from proof-terms we can also consistently add functions given by explicit definitions but in the general case, proving consistency can be very difficult. The great advantage of the above process is that when we add a new function defined by a program obtained from a proof-term, then consistency is guaranteed.

**Example (cont.).** We extract a program from our proof of (7):

\[
\varnothing \vdash_{\text{Sp}} \texttt{unextract}(f, \text{Sp}) : \exists y : \text{Nat} \cdot y \geq s(s(s(0)))
\]

where \( \text{Sp} \equiv \text{NewSpec(\text{Nat}_{A} \text{ and Nat}_{B} \text{ and Nat}_{C}, \exists y : \text{Nat} \cdot y \geq s(s(s(0))), \text{extract((a+b,k'))))} \).

By Theorem 2, \( \text{Sp} \) is a refinement of \( \text{Nat}_{A} \text{ and Nat}_{B} \text{ and Nat}_{C} \), \( \exists y : \text{Nat} \cdot y \geq s(s(s(0))), \text{extract((a+b,k'))} \).

By Theorem 2, \( \text{Sp} \) is a refinement of \( \text{Nat}_{A} \text{ and Nat}_{B} \text{ and Nat}_{C} \) which includes the function symbol \( f \) for the program extracted from \( (a+b, k) \). In CASL syntax, \( \text{Sp} \) appears as follows:

spec \( \text{Sp} = \)
\[
\{ \text{Nat}_{A} \text{ and Nat}_{B} \text{ and Nat}_{C} \text{ then}
\quad \text{ops } f : \text{Nat}
\quad \text{axioms } f = a + b
\quad \text{f } \geq s(s(s(0))))
\}
\]

end

Two axioms are given for \( f \) in \( \text{Sp} \): the equational (executable) definition and the Skolemized version of \( \exists y : \text{Nat} \cdot y \geq s(s(s(0))) \).

**Eliminating Critical Subterms.** As has been noted, we are unable to use the rule (Sk) to extract a program directly from a term involving critical terms such as (8). If we were permitted to use (Sk) on (8), then the equational definition \( f = a + b \) would be added as an axiom to the specification \( \text{Nat}_{C} \). This axiom involves symbols which are
not visible in the signature and here adding such an axiom to a specification would result in a specification that was not well formed.

Critical terms occur often using program extraction because we use functions from other specifications. In order to achieve a refinement of a target specification, these functions are often hidden.

There are two methods for eliminating critical terms from a proof term. 1. uses the extraction rule (Sk) and involves introducing an extra function for each such term and 2. involves adding new assumptions which will be satisfied by any suitable specification.

**Method 1.** Using the **extract** and **unextract** maps given above, we can transform any proof term into one which contains no critical terms. However, in this case we shall acquire an extra function and definition or axiom. We first show how this may be done.

**Lemma 3.** Given any term $\emptyset \vdash_{Sp} d : A$, there is a term $\emptyset \vdash_{Sp} \psi(d) : A$ such that $\psi(d)$ contains no critical subterms and $Sp \rightsquigarrow Sp'$.

Proof. We give a recursive definition of $\psi(d)$ using a depth-first traversal of the proof tree represented by $d$. Let $n(t)$ be the total number of critical subterms in the proof-term $t$. We define a terminating sequence of proof terms $d = d_0, ..., d_k = \psi(d)$. Given $d_i$, we determine $d_{i+1}$ as follows.

*Case 1.* If $d_i$ does not contain any critical subterm, then $d_{i+1} = \psi(d) = d_i$ (viz, the sequence terminates).

*Case 2.* Otherwise, normalize $d_i$ to give a proof term $d'$. As long as $d_i$ has no assumptions, the normalized proof term $d'$ will contain no subterms of the form $(\lambda x : A, p) \text{hide } \Sigma$. 1. Take the leftmost innermost critical subterm of the form $t = e \text{ hide } \Sigma : B$ in $d'$. That is, take the first critical subterm $t$ in $d'$ which does not contain any critical subterms. So, $e$ itself contains no critical subterms.

2. Apply (Sk) to $e : B$ to yield a new program $f = \text{extract}(e)$. Let $Sp \equiv \text{NewSpec}(sp(e), B, \text{extract}(e))$. Then, in $t$, replace $e$ by $\text{unextract}(f, Sp)$, and replace all occurrences of $\Sigma$ by $\Sigma \cup \{f\}$ to give $t'$.

3. Replace all occurrences of $t$ by $t'$ in $d'$, to give $d_{i+1} = d'[t'/t]$. The $d_{i+1}$ has at least one less critical subterm than $d_i$, and proves the same theorem as $d_i$.

Since $n(d_{i+1}) < n(d_i)$, this process yields a $k$ such that $n(d_k) = 0$. Then we take $\psi(d) = d_k$, which is a proof term with no critical subterms. $\square$.

Note that $Sp' = sp(d')$ and will be a conservatively correct refinement of $Sp$ by the definition of **extract**. The final specification will be a refinement of $sp(d)$. So, as a corollary of this lemma and our (Sk) rule, we can extract a program from any proof. First, we apply the procedure outlined in this lemma to remove critical subterms. Then we apply (Sk) to extract the program.

**Example (cont.).** If we apply the procedure of Lemma 3 to (8), we obtain the proof-term

$$\vdash^{\text{Nat}_{A'}} \text{hide}_{a,b} (\text{unextract}(f, \text{Nat}_{A'}), k') \text{ hide } a,b : \exists y : \text{Nat} \bullet y \geq s(s(s(0))))$$

where $\text{Nat}_{A'}$ is

$$\text{NewSpec} (\text{Nat}_A \text{ and } \text{Nat}_B \text{ and } \text{Nat}_C, \exists y : \text{Nat} \bullet y \geq s(s(s(0))), \text{extract}(a + b))$$

As can be seen, this new term contains no critical subterms. If we now extract a program from this term using (Sk), we obtain the following executable specification:

Note that $t'$ proves the same theorem as $t$ by Lemma 2 above and the definition of **unextract**, and is not a critical term.
spec \[ \text{NAT}_C' = \]
\{ \text{NAT}_A \text{ and } \text{NAT}_B \text{ and } \text{NAT}_C \text{ then} \\
ops \( f : \text{Nat} \) \\
axioms \( f = a + b \) \\
\( f \geq s(s(s(0))) \)
\} \\
hide a, b 
end

This is a conservatively correct refinement of \( \text{NAT}_C \) (and of \( \text{NAT}_C' \)) as required.

\textbf{Method 2.} There is an alternative means of eliminating critical terms. This involves transforming a proof by replacing (hide) rules with (Ass-I) rules. The disadvantage of this method is that although we may have established a formal proof for a formula to which we apply hide, we lose this information by taking the formula proved as a new assumption. We omit the details.

\textbf{Executable Refinements.} We refine a specification \( \text{Sp}_{\text{start}} \) to an executable specification \( \text{Sp}_{\text{ex}} \). Then \( \text{Sp}_{\text{ex}} \) is said to be \textit{executable} if every function in the signature has an equational definition in \( \text{Ax}(\text{Sp}_{\text{ex}}) \) of the form \( f = t \) (where \( t \) is a term in \( \Lambda \)). Recall (see Remark 5, footnote 13, above) that each valid proof-term \( \bar{t} \) has an associated structured specification \( \sp{\bar{t}} \). We use this property and our extraction rule (Sk) to produce the required executable refinement.

\textbf{Theorem 3 (Executable refinements).} Given a specification \( \text{Sp}_{\text{start}} \). If every un-Skolemized axiom in \( \text{Ax}(\text{Sp}_{\text{start}}) \) is constructively provable in our calculus (possibly using other specifications), then there is an executable specification \( \text{Sp}_{\text{ex}} \) which is a conservatively correct refinement of \( \text{Sp}_{\text{start}} \).

Proof. We construct a finite series of refinements \( \text{Sp}_{\text{start}} = \text{Sp}_1 \leadsto ... \leadsto \text{Sp}_k = \text{Sp}_{\text{ex}} \). Given a specification \( \text{Sp}_1 \), we obtain \( \text{Sp}_{1+1} \) as follows.

1. Take the first function symbol \( g \in \text{sig}(\text{Sp}_1) \) which is not a constructor for a sort and does \textit{not} have an executable definition in \( \text{Ax}(\text{Sp}_1) \).
2. Take the conjunction of all the axioms in \( \text{Ax}(\text{Sp}) \) in which \( g \) occurs.
3. UnSkolemize this conjunction. This will produce a formula of the form \( A \equiv \forall \overline{x} \exists y \cdot P(\overline{x}, y) \).
4. The proof of this conjunction gives a proof-term of the form \( \vdash_{\text{Sp}_1} d : A \) such that its structured specification \( \sp{d} \) has exactly the same\(^{30} \) signature as \( \text{Sp}_1 \).

Now let \( \text{Sp}_{1+1} \) be \( \text{Sp}' \) with \( \rho \) where \( \rho \) is the translation given by \( f_A \mapsto g \). Then \( \text{Sp}_{1+1} \) is a refinement of \( \text{Sp}' \). \( \text{Sp}_{1+1} \) will contain an (executable) declaration of the form \( \forall \overline{x} \ g(\overline{x}) = p(\overline{x}) \) (where \( \overline{x} \) is the list of variables in \( p \)). \( \text{Sp}_{1+1} \) has one less non-executable function in its signature than \( \text{Sp}' \).

Repeating the process yields a finite strict chain of refinements in which all functions of \( \text{Sp} \) have executable definitions.

Note: The definitions of the functions in \( \text{Sp}_{\text{ex}} \) are relatively executable in the sense that they may use non-executable functions in other (sub-)specifications.

\textbf{Example (cont.)} In \( \text{NAT}_C' \) with \( \rho \) where \( \rho \) is the translation given by \( f \mapsto c \), we have the required executable refinement of \( \text{NAT}_C \).

\textbf{Program Modules.} It would be desirable to take such an executable specification and to map it to a set of programs (a module) which have a structure that mirrors the structure

\(^{30}\) Note that the proof may use any axioms from \( \text{Sp}_1 \) except those in which \( g \) occurs.
of the executable specification. For the purposes of this paper we define a simple modular programming language with a clear semantics that supports union, translation and hiding of modules.\footnote{\textit{Programs} here means terms of our simply typed lambda calculus $\Lambda$.}

Formally, we take a basic program module to be defined by tuples of declarations. A declaration is an equality between a unique typed identifier $f : T$ and a program $p : T$ (where the types of $f$ and $p$ must coincide): $f = p$

A generic module is a lambda abstraction from program modules to program modules. So a non-generic module is either a basic program module, or is formed from other non-generic modules via the operations of translating $M$ with $\rho$, taking the union $M$ and $M'$ and hiding $M$ hide $\Sigma$ (where $M$, $M'$ are non-generic modules, $\Sigma$ is a symbol list and $\rho$ is a symbol map).

Here is the BNF notation for modules:

\[
\begin{align*}
  &\text{Program} ::= \text{A-term} \\
  &\text{Name} ::= \text{typed function variable} \\
  &\text{Sig} ::= \text{Name} \mid \text{Sig} \times \text{Name} \\
  &\text{Declaration} ::= \text{Name}^* = \text{Program} \\
  &\text{ModuleContents} ::= \text{Declaration} \mid \text{ModuleContents} \times \text{ModuleContents} \\
  &\text{Module} ::= \text{ModuleContents} : \text{Spec} \mid \text{Module and Module} \mid \text{Module with } \rho \mid \text{Module hide } \Sigma \mid \text{ModuleVar} \\
  &\text{GenericModule} ::= \lambda \text{ModuleVar}. \text{Module} \mid \lambda \text{ModuleVar}. \text{GenericModule} \\
  &\text{ModuleVar} ::= \text{Variable} : \text{Spec}
\end{align*}
\]

where $\text{Spec}$ ranges over structured specifications, $\Sigma$ ranges over symbol lists, and $\rho$ ranges over symbol maps.

Notes: 1. A program declared in a module may contain references to functions not declared within the same module. 2. The operator $\rho$ can be thought of as a module \textit{adapter}, which allows for modules to be reused with different names for functions. If we were to apply any translating maps to specifications prior to making them into modules, then there would be no need to add translating to the syntax of the language.

We place the following restrictions on modules:\footnote{These restrictions could be relaxed. Note that generic modules allow us to express higher order dependence\ of functions on functions, but that this dependence is not \textit{explicitly} revealed in the typing of name-program pairs.} 1. Semantically, generic modules are abstractions over basic (flat) program modules only. Higher order abstraction is not permitted. 2. The type of each name-program pair in any module must be first order. Higher order types are not permitted.

\textbf{Extracting Modules from Specifications.} We can extract a basic module from a basic executable specification $\text{Sp}$ simply by taking all function definitions as declarations in the module. We build a structured module from a structured specification by mapping the structure building operators of the specification to the corresponding operators of the module. One problem is that the declarations may contain references to functions of specifications that are not executable. We treat these specifications as module variables, and abstract over them at the end of the process to produce a generic module. This process will give us the following theorem.

\textbf{Theorem 4 (Extracting Program Modules).} \textit{Given an executable specification $\text{Sp}$, there exists a (possibly generic) module $M \equiv \lambda X_1 : \text{Sp}_1, \ldots, \lambda X_N : \text{Sp}_N.M'$ such that $M[U_1 : \text{Sp}_1, \ldots, U_N : \text{Sp}_N]$ is a realization of $\text{Sp}$ if each $U_I$ is a realization of $\text{Sp}_I$ for $I = 1, \ldots, N$. When $N = 0$, $M \equiv M'$, a realization of $\text{Sp}$.}
Proof. $M$ is the result of the recursive procedure \textit{GetModule} applied to \textit{Sp}. At the same time \textit{GetModule} will give us a list of variables $BV(\text{Sp}) = \{X_1 : \text{Sp}_1, ..., X_n : \text{Sp}_N\}$.

1. If \textit{Sp} is basic and executable, then \textit{GetModule}(\textit{Sp}) is the module obtained by taking all declarations in \textit{Sp} as declarations in the module. $BV(\text{Sp}) = \emptyset$. Clearly \textit{GetModule}(\textit{Sp}) is a realizer of \textit{Sp}.

2. If \textit{Sp} is basic and not executable, then \textit{GetModule}(\textit{Sp}) is a module variable $X : \text{Sp}$. $BV(\text{Sp}) = \{X : \text{Sp}\}$.

3. If \textit{Sp} is of the form $\text{Sp}_1$ and $\text{Sp}_2$ then \textit{GetModule}(\textit{Sp}) = \textit{GetModule}(\textit{Sp}_1) and \textit{GetModule}(\textit{Sp}_2). $BV(\text{Sp}) = BV(\text{Sp}_1) \cup BV(\text{Sp}_2)$.

4. If \textit{Sp} is of the form $\text{Sp}_1$ hide $\Sigma$, then \textit{GetModule}(\textit{Sp}) = \textit{GetModule}(\textit{Sp}_1) hide $\Sigma$. $BV(\text{Sp}) = BV(\text{Sp}_1)$.

5. If \textit{Sp} is of the form $\text{Sp}_1$ with $\rho$, then \textit{GetModule}(\textit{Sp}) = \textit{GetModule}(\textit{Sp}_1)$ with $\rho$. $BV(\text{Sp}) = BV(\text{Sp}_1)$.

Finally, let $M$ be given $M \equiv \lambda X_1 : \text{Sp}_1, ..., \lambda X_n : \text{Sp}_N$.\textit{GetModule}(\textit{Sp}) where $BV(\text{Sp}) = \{X_1 : \text{Sp}_1, ..., X_n : \text{Sp}_N\}$.

The rest of the proof follows from the definition of generic modules, and the fact that if \textit{Sp} is a basic executable specification, then \textit{GetModule}(\textit{Sp}) is obviously a realizer for \textit{Sp}.

If \textit{Sp} and all its subspecifications are executable, then $BV(\text{Sp}) = \emptyset$, $N = 0$ and $M$ is a non-generic module. □

\textbf{Example (cont.)}. The executable specification \texttt{NAT.C} is mapped to the following module using the algorithm of Theorem 4: \textit{GetModule}($\texttt{NAT.C}$) =

\[
\lambda X_1 : \text{NAT.A} \; \lambda X_2 : \text{NAT.B} \\
\; ( \\
\quad X_1 \; \text{and} \; X_2 \; \text{and} \\
\quad f = a + b \\
\quad c = f \\
\; ) \; \text{hide} \; a, b)
\]

Because \texttt{NAT.A} and \texttt{NAT.B} are not executable specifications, they correspond to module variables $X_1$ and $X_2$ respectively. If we can find modules which realize these specifications, then we can instantiate this generic module, obtaining a working program which computes $c$. The programs for $a$ and $b$ are encapsulated in \textit{GetModule}($\texttt{NAT.C}$). However, the function $f$ is not encapsulated (although its definition is). So, $c = f$ is a correct definition of $c$ that respects the encapsulation of the two submodules.

\textbf{Design Considerations}. We have seen how specification building operations correspond to module building operations. The location of the (hide) rules breaks the proof up into sections which correspond to modules: once the location of the (hide) rule is fixed, the design decision has been made. In the present procedure the proof process corresponds to a module design process where fixed decisions are made with respect to the placement of the (hide) rules. The application of (hide) in a proof corresponds to a design decision about the encapsulation of the resulting modules which will be extracted. However it is possible to move the other structural rules up and down proofs (see [18]). For example, if a logical argument is reused for several different specifications, then it will probably be convenient to leave all the translations to the end of the proof. We shall also normally try to move all the translations together into one large translation.
5 Conclusion

In this paper we have described a method which combines the techniques of structured specifications and program extraction in order to produce correct programs from structured specifications. As Sannella pointed out to us after seeing [18], it is not possible to separate the structural rules for building specifications from the logical rules in a proof completely. Nevertheless it is possible to provide a modified proof which gives rise to program modules. These modules are principally determined by the location of the applications of hiding (or export, as it was in [18]). We have shown how this can be done and illustrated the technique by a very simple example.33

The Curry-Howard technique we have used gives rise, in its simplest form, to very complicated programs. However, by the heavy use of techniques dependent on Harrop formulae we are able to reduce this dramatically. We have partially implemented our system and it produces readable programs, with a highly modular structure, in ML, directly from proofs.

The techniques we use are readily extended to systems with induction (and therefore recursion in the programs).

We have presented our work in the context of CASL and a logical system which is very standard so that it will be as easy as possible to read.

33 In a planned journal article we shall give much more substantial examples.
Appendix: Reduction Rules and Extracting Programs

Here we briefly supplement the description of the extraction of programs from proof-terms of § 4. In obtaining programs there are two stages that need to be distinguished. One is the normalization process of the logical (and structural) calculus which uses the logical and structural reductions and proceeds in a standard way as in [7] and [1].) This produces a simplified proof-term. After this there is the actual extraction of the program.

Normalizing reductions There are two types of normalizing reductions: those for logical rules which follow the traditional pattern initiated by Curry and Howard (see, e.g. [7]), and those for structural rules initiated by us in [18]. We also briefly mention the permutation of rules mentioned at the end of § 4. (We omit brackets and the intial $\Gamma \vdash_{SP}$ as $\Gamma$ and Sp can be found by applying the function $sp$ to the term. (See footnote 11, remark 5.)

Logical Reductions

For each connective we can reduce when an introduction is immediately followed by an elimination. In § 4 we explicitly showed how ($\land$-I) followed by ($\land$-E) reduces. The corresponding reductions for the other connectives are as follows:

<table>
<thead>
<tr>
<th>Operation</th>
<th>Reducibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\land$</td>
<td>$\pi_1(\langle a_1 : A_1, a_2 : A_2 \rangle) \vdash a_i : A_i$ for $i \in {1,2}$</td>
</tr>
<tr>
<td>$\rightarrow$</td>
<td>$(\lambda x : A.d : (A \rightarrow B))(a : A) \vdash d[a/x] : B$</td>
</tr>
<tr>
<td>$\forall$</td>
<td>$(\lambda x : s.d : (\forall x : s \rightarrow B))(a : s) \vdash d[a/x] : B[a/x]$</td>
</tr>
<tr>
<td>$\exists$</td>
<td>$\text{select}(z : s,y : A[z/x],e : C,d : \exists x : s \cdot A) : C \vdash e[\pi_1(d)/z][\pi_2(d)/y] : C$</td>
</tr>
</tbody>
</table>

Structural reductions

These are commonsense reductions: two translations can be consolidated into one; and enriching by $\Sigma$ and then hiding $\Sigma$, or vice versa, reduces to a triviality.

For $i \in \{1,2\}$ and $\Sigma \subseteq \text{Sig}(SP)$:

<table>
<thead>
<tr>
<th>Operation</th>
<th>Reducibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>Composition</td>
<td>$(\rho_2 \circ (\rho_1 \cdot d : \rho_1(A))) : \rho_2(\rho_1(A)) \vdash \rho' \cdot d : \rho'(A)$ where $\rho' = \rho_2 \circ \rho_1$</td>
</tr>
<tr>
<td>$\text{hide/enrich}_i$</td>
<td>$\text{enrich}_i((d : A \text{ hide } \Sigma) : A,\text{ SP}) : A \vdash d : A$</td>
</tr>
<tr>
<td>$\text{enrich}_i/\text{hide}$</td>
<td>$\text{enrich}_i(d : A,\text{ SP}) \text{ hide sig}(\text{SP}) : A \vdash d : A$</td>
</tr>
</tbody>
</table>

Program Extraction

First we define the types for our lambda calculus by:

$$\tau, \tau_1, \tau_2, \tau_3 := s \mid \tau_1 \times \tau_2 \mid \tau_1|\tau_2 \mid H$$

where $s$ ranges over the set of sorts.

Terms of $\Lambda$ are given by the following grammar

$$t_1, t_2, t_3 ::= \alpha \mid t \mid () \mid \pi_1 t_1 \mid \pi_2 t_2 \mid \lambda x : \tau.t_1 \mid \langle \pi_1, t_1 \rangle \mid \langle \pi_2, t_1 \rangle \mid (t_1, t_2) \mid t_1 t_2 \mid \text{case}(x : \tau_1, t_1, y : \tau_2, t_2, t_3) \mid \text{select}(x : \tau_1, y : \tau_2, t_1, t_2)$$

where $\alpha$ ranges over terms whose sort is in $s$ and $x$ ranges over variable names.

---

34 The explicit formulations of the reductions in the logical proofs are given in, for example, [7].
The type formation rules for $\Lambda$ are as follows.

\[
\begin{align*}
\vdash () & : H \\
\alpha : s & \quad \frac{}{x : s \vdash x : s}
\end{align*}
\]

where $\alpha$ is a term of sort $s$.

\[
\begin{align*}
\Gamma, x : \tau_1 & \vdash t \\
\Gamma & \vdash \lambda x : \tau_1.t \\
\Gamma, x : \tau_1 & \vdash t : \tau_1 \\
\Gamma, y : \tau_2 & \vdash e : \tau \\
\Gamma, y : \tau_2 & \vdash f : \tau_1\tau_2 \\
\Gamma, y : \tau_2 & \vdash e : \tau \\
\Gamma & \vdash (\pi, t_i) : \tau_i \\
\Gamma & \vdash (\pi, t_i) : \tau_i \\
\Gamma & \vdash (\pi, t_i) : \tau_i \\
\Gamma & \vdash (\pi, t_i) : \tau_i \\
\Gamma & \vdash (\pi, t_i) : \tau_i \\
\Gamma & \vdash (\pi, t_i) : \tau_i \\
\Gamma, x : \tau_1 & \vdash d : \tau \quad \Gamma, y : \tau_2 & \vdash e : \tau \\
\Gamma, y : \tau_2 & \vdash f : \tau_1\tau_2 \\
\Gamma & \vdash \text{case}(x : \tau_1.d, y : \tau_2.e, f) : \tau \\
\Gamma, x : \tau_1, y : \tau_2 & \vdash e : \tau \\
\Gamma & \vdash f : \tau_1\tau_2 \\
\Gamma & \vdash \text{select}(x : \tau_1, y : \tau_2.e, f) : \tau
\end{align*}
\]

The operational semantics of $\Lambda$ is given below. (These are the usual reduction rules for simply typed lambda calculus augmented by product and union types).

\[
\begin{align*}
(\lambda x : \tau_1.d) r & \rightarrow d[r/x] \\
\text{case}(x_1 : \tau_1.d_1, x_2 : \tau_2.d_2, (\pi_i, f)) & \rightarrow d_i[f/x_i] \quad \text{for } i \in \{1, 2\} \\
\text{select}(x : \tau_1.y : \tau_2.d, (a, b)) & \rightarrow d[a/x][b/y] \\
\pi_i(t_1, t_2) & \rightarrow t_i \quad \text{for } i \in \{1, 2\}
\end{align*}
\]

We define a map $\phi$ over formulae of our logical system to types of $\Lambda$. Given a formula $F$, $\phi(F)$ will give us the (computational) type of the program extracted from the proof of $F$. $\phi$ is defined by cases.

If $A$ is Harrop, then $\phi(A) = H$, otherwise, $\phi$ is defined as below.

\[
\begin{align*}
\phi(\exists x : s \bullet A) & = \begin{cases} s & \text{if}\ Harrop(A) \\ s \times \phi(A) & \text{otherwise} \end{cases} \\
\phi(V x : s \bullet A) & = \lambda x : s.\phi(A) \\
\phi(A \rightarrow B) & = \begin{cases} \phi(B) & \text{if}\ Harrop(A) \\ \phi(A) \rightarrow \phi(B) & \text{otherwise} \end{cases} \\
\phi(A \land B) & = \begin{cases} \phi(A) \times \phi(B) & \text{if}\ Harrop(A) \\ \phi(A) \times \phi(B) & \text{otherwise} \end{cases} \\
\phi(A \lor B) & = \phi(A)\mid\phi(B)
\end{align*}
\]
\[
\begin{align*}
\text{extract}(\text{ass}(A, x) : A) &= \begin{cases} 
\emptyset \\
\{ x \} 
\end{cases} & \text{if Harrop}(A) \\
\text{otherwise}
\end{align*}
\]
\[
\begin{align*}
\text{extract}(\text{ax}(\Sigma, Ax), x) : A) &= \begin{cases} 
\emptyset 
\end{cases}
\end{align*}
\]
\[
\begin{align*}
\text{extract}(\lambda x : A : d) : A \rightarrow B) &= \begin{cases} 
\emptyset \\
\lambda x : \phi(A), \text{extract}(d) 
\end{cases} & \text{if Harrop}(A) \\
\text{if Harrop}(A \rightarrow B) \\
\text{otherwise}
\end{align*}
\]
\[
\begin{align*}
\text{extract}((a, b) : A \land B) &= \begin{cases} 
\text{extract}(a) \\
\text{extract}(b) \\
\emptyset
\end{cases} & \text{if Harrop}(A) \\
\text{and not Harrop}(B) & \text{if Harrop}(B) \\
\text{and not Harrop}(A) & \text{if Harrop}(A \land B) \\
\text{otherwise}
\end{align*}
\]
\[
\begin{align*}
\text{extract}((\lambda x : s : d) ; \forall x : S B) &= \begin{cases} 
\emptyset \\
\lambda x : s, \text{extract}(d)
\end{cases} & \text{if Harrop}(\forall x : S \bullet B) \\
\text{otherwise}
\end{align*}
\]
\[
\begin{align*}
\text{extract}((t, d) : \exists x : s \bullet A) &= \begin{cases} 
\emptyset \\
(t, \text{extract}(d))
\end{cases} & \text{if Harrop}(A) \\
\text{otherwise}
\end{align*}
\]
\[
\begin{align*}
\text{extract}((\pi_1, d : A_1) : A_1 \lor A_2) &= (\pi_1, \text{extract}(d))
\end{align*}
\]
\[
\begin{align*}
\text{extract}((\pi_2, d : A_1) : A_1 \lor A_2) &= (\pi_2, \text{extract}(d))
\end{align*}
\]
\[
\begin{align*}
\text{extract}((d : A \rightarrow B)(r : A) : B) &= \begin{cases} 
\emptyset \\
\text{extract}(d)
\end{cases} & \text{if Harrop}(A) \\
\text{if Harrop}(A \rightarrow B) \\
\text{otherwise}
\end{align*}
\]
\[
\begin{align*}
\text{extract}((d : \forall x : s \bullet B(x))(r : s) : B[r/x]) &= \begin{cases} 
\emptyset \\
\text{extract}(d)[r]
\end{cases} & \text{if Harrop}(B[d/x]) \\
\text{otherwise}
\end{align*}
\]
\[
\begin{align*}
\text{extract}((\text{case}(x : A, d : C), y : B, e : C, f : (A \lor B)) : C) &= \begin{cases} 
\emptyset \\
\text{case}(\text{extract}(x), \text{extract}(d), \\
\text{extract}(y), \text{extract}(e), \text{extract}(f))
\end{cases} & \text{if Harrop}(C) \\
\text{otherwise}
\end{align*}
\]
\[
\begin{align*}
\text{extract}(\text{select}(z : s, y : A[z/x], e : C, d : \exists x : s, A) : C) &= \begin{cases} 
\emptyset \\
(\lambda x : s, \text{extract}(e)) \text{extract}(d)
\end{cases} & \text{if Harrop}(C) \\
\text{if Harrop}(A) \\
\text{otherwise}
\end{align*}
\]
\[
\begin{align*}
\text{extract}(\text{union}(d, SP)) &= \text{extract}(d) \\
\text{extract}(\rho \bullet d) &= \text{extract}(\rho(d)) \\
\text{extract}(d \text{ hide } l) &= \text{extract}(d)
\end{align*}
\]

Fig. 3. The definition of extract.

The definition for \textbf{extract} is in Fig. 3. It assumes the proof-terms are \textit{modular}.

Note that the final specification and the list of assumptions can easily be computed from the original proof-term.
