Finite-Time Event-Triggered $\mathcal{H}_\infty$ Control for T-S Fuzzy Markov Jump Systems

Hao Shen, Feng Li, Hamid Reza Karimi, Senior Member, IEEE, and Hak-Keung Lam, Senior Member, IEEE

Abstract—This paper investigates the finite-time event-triggered $\mathcal{H}_\infty$ control problem for Takagi-Sugeno Markov jump fuzzy systems. Because of the sampling behaviors and the effect of the network environment, the premise variables considered in this paper are subject to asynchronous constraints. The aim of this work is to synthesize a controller via an event-triggered communication scheme such that not only the resulting closed-loop system is finite-time bounded and satisfies a prescribed $\mathcal{H}_\infty$ performance level, but also the communication burden is reduced. Firstly, a sufficient condition is established for the finite-time bounded $\mathcal{H}_\infty$ performance analysis of the closed-loop fuzzy system with fully considering the asynchronous premises. Then, based on the derived condition, the desired controller design method is presented. Finally, two illustrative examples are given to explain the practicability and availability of the designed controller.

Index Terms—Markov jump fuzzy systems, finite-time control, event-triggered $\mathcal{H}_\infty$ control, asynchronous premises.

I. INTRODUCTION

In the last several decades, Markov jump systems (MJSs) have developed into an actively investigated topic in the control and system community. This is due mainly to the fact that many practical systems experiencing random changes in their parameters or structures are very appropriately described by MJSs. A Markov jump system is composed of many interconnected subsystems, and the information exchange among these subsystems is governed by the Markov chain or Markov process. Hence, MJSs could be regarded as a particular class of hybrid stochastic systems. The typical applicable examples for such systems can be found in a broad range of areas, such as networked control systems (NCSs), economic systems and power systems [1], [4], [26]. In this context, therefore, a large number of researchers have endeavored to investigate MJSs and quantities of related results have been acquired, see, e.g., [6], [11], [13], [16], [22], [37], [38]. However, it is recognized that many obtained research results are just available for the linear MJSs owing to the inherent complex characteristics of nonlinear MJSs. Thanks to the presented Takagi-Sugeno (T-S) fuzzy model [5], [8], [9], [19], [24], [31], [41], such complex nonlinear MJSs could be successfully represented in an easy-to-investigate form. As a consequence, it is not surprising that the past years have witnessed a surge of research interest in the study of nonlinear MJSs by using the fuzzy-model-based approach. For details on research advances about this issue, we refer readers to [3], [20], [28] and the references therein.

It is worth noting that all the aforementioned results related to the primary stability analysis and control issues for MJSs, especially for fuzzy Markov jump systems (FMJSs), are concentrated on Lyapunov asymptotic stability (LAS). The LAS, as is known, is mainly described as the infinite time interval asymptotic behavior of the state trajectories. Actually, it would not be suitable in some scenarios, where the control objective is to make sure that during a fixed time-interval, the states of system keep in assigned threshold values. For example, the orbital control of a space vehicle from an initial position to the object region was discussed in [2]. Therefore, the finite-time stability emerged from the far-reaching work of [7] has received extensive attention during the past decades, such as finite-time stability and stabilization [2], finite-time filtering and state estimation [40], finite-time control [12], to name a few. Despite the significance of the finite-time stability has been acknowledged, there appears little progress toward on this issue for FMJSs, which is one of the motivations behind this work.

On the other hand, as an irresistible trend, in modern control systems, the data among the sensors, controllers, and actuators are frequently transmitted through a shared communication network. The insertion of the network can offer many advantages including reduced equipment weight, lower deployment costs and easy maintenance. Such benefits have given a tremendous amount of motivations to extensive applications of NCSs [10], [21], [29], [32], [39]. It should be remarkable that the communication bandwidth of the shared communication network, as a scarce resource in NCSs, is usually limited. In the widely used time-triggered control, all the sampled data (SD) are required to be transmitted and the actuator state is adjusted at each sampling instant (SI). However, when the states of the controlled plant have arrived or are close to the equilibrium point and no exogenous disturbance input exists, there is little effect of the sensor measurement signal on system performances over those specific time interval. In this case, some unnecessary SD may be generated. Undoubtedly, transmitting those unnecessary SD reduces the efficiency of communication and leads to unnecessary energy consumptions. To cope with this problem, the event-triggered communication scheme (ETCS), as an alternative communication scheme, has been introduced to overcome the shortcomings.

Manuscript received ; revised .
of the time-triggered control strategy. Such a communication scheme can efficiently utilize the communication bandwidth since that the transmissions of the SD between the controller and the plant occur only when a predefined event triggering condition is satisfied rather than periodically as the case of traditional setups. Up to now, a growing number of works have been devoted to this topic [23]. To mention a few, to reduce communication burdens, Wen et al. used an event-triggered control method to study the load frequency control for multi-area power systems in [30]; a discrete event-triggered scheme was proposed to investigate the $H_{\infty}$ controller design for linear NCSs in [33] and then expanded to the case of networked T-S fuzzy systems (NTSFSs) in [18]. It should be mentioned that how to use such a method to deal with the $H_{\infty}$ controller design for FMJSs in the sense of finite-time stability is still challenging.

Moreover, many works reported in the area of NTSFSs are on the basis of the assumption that the controller/filter completely shares the same premise variables with plant [25]. However, such an assumption cannot be satisfied in NTSFSs because of the sampling behaviors and the effect of network environment. Owing to this reason, the asynchronous premises have been taken into consideration when concerning with the modeling, analysis and control of NTSFSs. For instance, the stability analysis was carried out in [15], the event-triggered $H_{\infty}$ filtering issue was considered in [36], and the event-triggered control problem was resolved in [18]. To the best of our knowledge, however, there are no solutions available to cope with the finite-time event-triggered $H_{\infty}$ control problems for FMJSs when such an asynchronous constraint is fully considered, and accordingly seeking satisfactory solutions to this problem is the another primary motivation of the present study.

Summarizing the above discussions, in this paper we are interested in addressing the finite-time event-triggered $H_{\infty}$ control problem for T-S FMJSs. The main contributions of this work lie in the following three aspects: 1) The ETCS, which covers the traditional time-triggered communication scheme (TTCS) as a special case by choosing some appropriate scalars (i.e., setting $\sigma_i \equiv 0$ in (5)), is employed to address the finite-time $H_{\infty}$ control problem for T-S FMJSs as a first attempt. 2) Different from some previous works in NTSFSs where the controller/filter completely shares the same premise variables with the plant, the asynchronous premises are here taken into account here. Due to the effect of the network environment, considering the asynchronous premises in NTSFSs is more appropriate with the actual situation than considering the synchronous ones. 3) Some auxiliary function-based integral inequalities are established, that provide much tighter bounds than Jensen inequality and the Wirtinger-based inequality.

With the help of those inequalities, some double integral terms could be reserved and less conservative results can be obtained, consequently. The rest of this paper is organized as follows. Section II formulates the problem. The design of the finite-time event-triggered $H_{\infty}$ controller for the considered FMJSs is carried out in Section III. The effectiveness and superiority of our developed scheme are demonstrated via two examples in Section IV. Section V concludes this paper, finally.

Notations. In this paper, the notations employed are fairly standard. $\mathbb{R}^n$ denotes the $n$-dimensional Euclidean space; for symmetric matrices $M$, the notation $M \geq 0$ (respectively, $M > 0$) means that the matrix $M$ is positive semi-definite (respectively, positive definite); $\lambda_{\min}(P)$ (respectively, $\lambda_{\max}(P)$) represents the smallest (respectively, largest) eigenvalue of symmetric matrix $P$; $E\{\cdot\}$ denotes the expectation operator; $\text{Sym}\{M\}$ represents $M+M^T$ and $\otimes$ denotes Kronecker product; 0 and $I$ stand for, respectively, the zero matrix and identity matrix with appropriate dimensions. The transpose of the matrix $M$ is represented by the notation $M^T$.

In complex matrix expressions or symmetric block matrices, we use an asterisk ($\ast$) to describe a term which is induced by symmetry.

II. PROBLEM FORMULATION

Fixing a probability space $(\Omega, \mathcal{F}, \mathcal{P})$, consider the following nonlinear Markov jump system represented by a T-S fuzzy model:

Plant Rule $i$: IF $\vartheta_1(t)$ is $\mu_{i1}$, and $\vartheta_2(t)$ is $\mu_{i2}$, and $\cdots,$ and $\vartheta_r(t)$ is $\mu_{ir}$, THEN

$$\dot{x}(t) = A_i(\vartheta(t))x(t) + B_i(\vartheta(t))u(t) + C_i(\vartheta(t))\omega(t),$$

$$z(t) = D_i(\vartheta(t))x(t) + F_i(\vartheta(t))u(t),$$

(1)

(2)

where the scalar $i = 1, 2, \cdots, r$, $r$ is the number of IF-THEN rules of the system; $\mu_{ij}(i = 1, 2, \cdots, r; j = 1, 2, \cdots, g)$ present the fuzzy sets and $\vartheta_j(t)$ ($j = 1, 2, \cdots, g$) are the premise variables. $x(t) \in \mathbb{R}^n$ and $z(t) \in \mathbb{R}^p$ are the system state vector and system output vector, respectively. $\omega(t) \in \mathbb{R}^q$ is the exogenous disturbance input that belongs to $L_2[0, \infty)$ and subjects to $\int_0^\infty \omega^T(t)\omega(t)dt \leq \bar{\omega}$. The parameter $\vartheta(t)$, which takes discrete values in a finite state space $\mathbb{M} = \{1, 2, \cdots, \bar{m}\}$, is a right continuous homogeneous Markov process and the jumping of $\vartheta(t)$ satisfies the transition probability matrix (TPM) $P = \{p_{lm}\}$ determined by

$$\Pr\{\vartheta(t+\Delta t) = m | \vartheta(t) = l\} = \left\{ \begin{array}{ll}
\pi_{lm}\Delta t + o(\Delta t), & l \neq m, \\
1 + \pi_{ll}\Delta t + o(\Delta t), & l = m.
\end{array} \right.$$

The dynamics of the fuzzy system model (1)-(2) can be derived as follows:

$$\dot{x}(t) = \sum_{i=1}^{r} h_i(\vartheta(t))[A_ix(t) + B_iu(t) + C_i\omega(t)],$$

$$z(t) = \sum_{i=1}^{r} h_i(\vartheta(t))[D_i x(t) + F_i u(t)],$$

(3)

(4)

where $h_i(\vartheta(t)) = \frac{\pi^{\vartheta}_{\vartheta(t)}}{\sum_{i=1}^{r} \pi^{\vartheta}_{\vartheta(t)}}$ is the fuzzy basis function, in which $\mu_{ij}$ ($\vartheta_j(t)$) is defined as the grade of membership of $\vartheta_j(t)$ in $\mu_{ij}$. For each $\delta(t) = l \in \mathbb{M}$, $A_{il}$, $B_{il}$, $C_{il}$, $D_{il}$ and $F_{il}$ are denoted as $A_{il} \triangleq A_i(\vartheta(t))$, $B_{il} \triangleq B_i(\vartheta(t))$, $C_{il} \triangleq C_i(\vartheta(t))$, $D_{il} \triangleq D_i(\vartheta(t))$, $F_{il} \triangleq F_i(\vartheta(t))$, respectively. To simplify the notation, in this work, it is denoted that $\Pi^{\vartheta}_{j=1} \mu_{ij}(\vartheta_j(t)) \geq 0$, $\sum_{i=1}^{r} \Pi^{\vartheta}_{j=1} \mu_{ij}(\vartheta_j(t)) > 0$. Thus, we
have \( h_i(\vartheta(t)) \geq 0 (i = 1, 2, \cdots, r) \) and \( \sum_{i=1}^{r} h_i(\vartheta(t)) = 1 \) for all \( t \).

In this paper, inspired by the work in [33], the event-triggered mechanism is that all the transmitted SD are time-stamped and only when the following condition is unsatisfied, the SD are transmitted to the controller: \( \omega_{\tau}(t_{k+1}h) = \sigma_{\Omega}(x(t_{k+1}h)) \Omega_{t}x(t_{k+1}h) \),

\[ \mathbf{e}_{k}^{T}(t_{k+1}h) \Omega_{k} \mathbf{e}_{k}(t_{k+1}h) < \sigma_{\Omega}(x(t_{k+1}h)) \Omega_{t}x(t_{k+1}h), \quad (5) \]

where \( \mathbf{e}_{k}(t_{k+1}h) \) is the error between the state \( x(t_{k+1}h) \) at the current SI and the state \( x(t_{k+1}h) \) at the latest transmitted SI, i.e., \( \mathbf{e}_{k}(t_{k+1}h) = x(t_{k+1}h) - x(t_{k+1}h) \). For \( l \in \mathbb{M} \), \( \sigma_{l} \) are given positive scalars and \( \Omega_{l} \) are symmetric positive matrices to be determined later.

**Remark 1:** According to (5), one can see that the next release time \( t_{k+1}h \) is determined by

\[ t_{k+1}h = t_{k}h + \min_{m \geq 1} \left\{ mh | \mathbf{e}_{k}^{T}(t_{k+1}h) \Omega_{k} \mathbf{e}_{k}(t_{k+1}h) < \sigma_{\Omega}(x(t_{k+1}h)) \Omega_{t}x(t_{k+1}h) \right\}, \]

where \( \mathbf{e}_{k}(t_{k+1}h) = x(t_{k+1}h) - x(t_{k+1}h) \). Therefore, the transmit interval is \( t_{k+1}h - t_{k}h \) and the SD obtained by sensors during the time interval \( (t_{k}, t_{k+1}) \) is not transmitted to the controller completely, which means the ETCS can reduce the bandwidth utilization.

**Remark 2:** It is easy to see that if we set \( \sigma_{l} \equiv 0 \), the condition (5) cannot be satisfied all the time. In other words, all the SD are transmitted to the controller. In this case, the ETCS degenerates to the case of TTCs.

Before further theoretical development, in this paper, some necessary assumptions are given below.

**Assumption 1:** [18] In the communication network, the sensors are assumed to be time-triggered with the trigger period \( h \). Meanwhile, the controller and actuators are event-triggered.

**Assumption 2:** The total network-induced delay considered in this paper is \( \hat{\tau}_{k,n} \), which is bounded and satisfies \( 0 < \hat{\tau}_{k,n} \leq \hat{\tau}_{M} \), where \( \hat{\tau}_{M} \) is a known constant. The holding time of a logic ZOH at the actuator is \( t \in \bar{\Omega}_{k} = [i_{k}h + \hat{\tau}_{k,n}, i_{k+1}h + \hat{\tau}_{k+1,n}] \), where \( x(t_{k}h + \hat{\tau}_{k,n}) \) is the instant when the control data packet reaches the ZOH.

Under the above assumptions, when \( t \in \bar{\Omega}_{k} = [t_{k}h + \hat{\tau}_{k,n}] \), the error between the future transmitted SI \( t_{k+1}h \) and the current transmitted SI \( i_{k}h \) can be deduced as

\[ e_{k}(t_{k}h) = x(t_{k}h) - x(t_{k}h), \]

where \( i_{k}h + \hat{\tau}_{k,n} \) is the SI between the above two states.

Define \( \tau(t) = t - t_{k}h \), then the expression of the transmitted state \( x(t_{k}h) \) can be described:

\[ x(t_{k}h) = x(t - \tau(t)) - e_{k}(t_{k}h), \quad (6) \]

In light of the above definition about \( \tau(t) \), it yields that \( \tau(t) = 1 \) for \( t \in \bar{\Omega}_{k} \) and

\[ 0 < \hat{\tau}_{k,n} \leq \tau(t) \leq h + \max \{ \hat{\tau}_{k,n}, \hat{\tau}_{k+1,n} \} = h + \hat{\tau}_{M} \equiv \Delta_{k}. \]

In this study, the fuzzy-model based state feedback controllers are designed as

**Control Rule i:** IF \( \vartheta_{1}(t_{k}h) \) is \( \mu_{11} \), and \( \vartheta_{2}(t_{k}h) \) is \( \mu_{22} \), and \( \cdots \), and \( \vartheta_{g}(t_{k}h) \) is \( \mu_{rg} \), THEN

\[ u(t) = K_{i}x(t_{k}h), \quad t \in [t_{k}h + \tau_{k,n}, t_{k+1}h + \tau_{k+1,n}], \]

where \( K_{i} \) are the desired controller gains to be determined for each \( i = 1, 2, \cdots, r. \) Then, the overall fuzzy controller can be represented by

\[ u(t) = \sum_{i=1}^{r} h_{i}(\vartheta(t_{k}h)) K_{i}x(t_{k}h). \]

**Remark 3:** Most of the existing works in the area of NTSFs contain the implicit assumption that the premise variables of fuzzy controller are consistent with the fuzzy model. Then the fuzzy controller is chosen as \( u(t) = \sum_{i=1}^{r} h_{i}(\vartheta(t_{k}h)) K_{i}x(t_{k}h) \). However, due to the sampling behaviors and the influence of the network environment, the membership functions of the controller and the plant are no longer equivalent in NBTsFs. For this consideration, in this work, the designed controller is chosen as the representation of (7) rather than \( u(t) = \sum_{i=1}^{r} h_{i}(\vartheta(t_{k}h)) K_{i}x(t_{k}h) \).

Substituting (6) into (7), we can obtain

\[ u(t) = \sum_{i=1}^{r} h_{j}(\vartheta(t_{k}h)) K_{i} [x(t - \tau(t)) - e_{k}(t_{k}h)]. \]

**Remark 4:** For asynchronous constraints (9), it is not difficult to find that when \( \phi = 1 \), \( \min_{j=1,2,\cdots,r} \{ \phi_{2} \} = \phi_{2} = \phi_{1} = \min_{j=1,2,\cdots,r} \{ \phi_{1} \} \), which means \( \phi_{j} \equiv 1 \). In other words, the membership functions of a fuzzy controller are always the same with the fuzzy model (1)-(2), i.e. \( h_{j}(\vartheta(t_{k}h)) = h_{j}(\vartheta(t)) \), which has been widely considered in the existing
literature. In this case, the controller is simplified into the gen-
eral point-to-point connected controller. Thus, the synchronous
premise can be deemed as a peculiar case of asynchronous
ones, which means that the considered asynchronous premise
for NTSFSs is more general in this paper.

Combining (1)-(2), (8) and (9), the closed-loop fuzzy system
(CLFS) \( \Sigma \) can be formulated as

\[
\begin{align*}
\dot{x}(t) &= A_1 x(t) + B_1 e(t, h_1) + C_1 \omega(t), \\
z(t) &= D_1 x(t) + F_1 e(t, h_2), \\
x(t) &= \varphi(t), t \in [-\tau_M, 0],
\end{align*}
\]

where

\[
\begin{align*}
A_1 &\triangleq \sum_{i=1}^r h_i A_{il}, & B_1 &\triangleq \sum_{i=1}^r \sum_{j=1}^r \rho_{ij} h_j B_{il} K_j, \\
C_1 &\triangleq \sum_{i=1}^r h_i C_{il}, & D_1 &\triangleq \sum_{i=1}^r h_i D_{il}, \\
F_1 &\triangleq \sum_{i=1}^r \sum_{j=1}^r \rho_{ij} h_j F_{il} K_j.
\end{align*}
\]

To describe the objective of this paper, the following lemmas
and definitions are introduced at first.

**Lemma 1:** [17] For any vectors \( \zeta_1, \zeta_2 \), matrices \( T > 0, F \),
and real scalars \( k_1 > 0, k_2 > 0 \) satisfying \( k_1 + k_2 = 1 \), the
following inequality holds:

\[
-\frac{1}{k_1} \zeta_1^T Y \zeta_1 - \frac{1}{k_2} \zeta_2^T Y \zeta_2 \leq -\begin{bmatrix} \zeta_1 \\ \zeta_2 \end{bmatrix}^T \begin{bmatrix} Y & F \\ * & Y \end{bmatrix} \begin{bmatrix} \zeta_1 \\ \zeta_2 \end{bmatrix},
\]

subject to

\[
\begin{bmatrix} Y & F \\ * & Y \end{bmatrix} > 0.
\]

**Lemma 2:** [35] The following condition:

\[
\begin{align*}
\Delta + \vartheta \Delta_1 &< 0, \\
\Delta + \vartheta \Delta_2 &< 0,
\end{align*}
\]

are equivalent to the inequality as follows

\[
\Delta + \epsilon \Delta_1 + (\vartheta - \epsilon) \Delta_2 < 0,
\]

where constant matrices \( \Delta, \Delta_1 \) and \( \Delta_2 \) are with appropriate
dimensions, \( \epsilon \in [0, \vartheta] \) and \( \vartheta > 0 \).

**Definition 1:** [12] Given two fixed scalars \( a_1 > 0, a_2 > 0 \)
and a positive matrix \( R > 0 \), system \( \Sigma \) with \( \omega(t) \equiv 0 \)
is of finite-time stable (FTS) with regard to \( (a_1, a_2, t_p, R) \), if the
following condition holds

\[
\sup_{-\tau_M \leq s \leq 0} E \{ x^T(s) R x(s), \dot{x}^T(s) R \dot{x}(s) \} \leq a_1,
\]

\[
\implies E \{ x^T(t) R x(t) \} \leq a_2, \quad \forall t \in [0, t_p].
\]

**Definition 2:** [12] Given three fixed scalars \( a_1 > 0, a_2 > 0, \omega > 0 \)
and a positive matrix \( R > 0 \), system \( \Sigma \) is of finite-
time bounded (FTB) with regard to \( (a_1, a_2, t_p, R, \omega) \), if the
following condition holds

\[
\sup_{-\tau_M \leq s \leq 0} \int_{0}^{t_0} \omega^T(t) \omega(t) dt \leq \omega
\]

\[
\implies E \{ x^T(t) R x(t) \} \leq a_2, \quad \forall t \in [0, t_p].
\]

**Definition 3:** [12] Given three fixed scalars \( a_1 > 0, a_2 > 0, \omega > 0 \)
and a positive matrix \( R > 0 \), system \( \Sigma \) is of FTB with
regard to \( (a_1, a_2, t_p, R, \omega) \) in Definition 2.
(a) under zero initial state and for any non-zero \( \omega(t) \in L_2 \), the following
condition is ensured:

\[
E \left\{ \int_{0}^{t_p} \omega^T(t) \omega(t) dt \right\} < \gamma^2 E \left\{ \int_{0}^{t_p} \omega^T(t) \omega(t) dt \right\}.
\]

With those definitions, the issue to be addressed in this work
could be formulated as follows: design a controller of form (7)
for the given system (1)-(2) such that the CLFS (10)-(12) is
FTB with regard to \( (a_1, a_2, t_p, R, \omega) \) and satisfies the given
\( \mathcal{H}_\infty \) performance level \( \gamma \) in Definition 3.

**III. MAIN RESULTS**

For the addressed problem in this paper, this section will
develop a controller design method. Firstly, a FTB \( \mathcal{H}_\infty \) performance
analysis criterion for the CLFS (10)-(12) is established. For presentation convenience, throughout this paper we denote
the following functions for \( \varsigma = 1, 2, \kappa = 1, 2, \ldots, 12 \)
and any matrix \( X \)

\[
\begin{bmatrix} 0 & \cdots & 0 \\ \kappa^{-1} & 0 & \cdots & 0 \\ & \vdots & \ddots & \vdots \\ & & & \kappa^{12-\kappa} \end{bmatrix},
\]

\[
\Gamma \triangleq [ \Gamma_1 \quad \Gamma_2 ], \Xi(X) \triangleq \text{diag} \{ \lambda', 3\lambda', 5\lambda' \}, \Gamma_\varsigma \triangleq \left[ (\vartheta_{2\varsigma-1} - \vartheta_{2\varsigma+2}) (\vartheta_{2\varsigma-1} + \vartheta_{2\varsigma+2} - 2\vartheta_{2\varsigma+4}) (\vartheta_{2\varsigma-1} + \vartheta_{2\varsigma+2} + 6\vartheta_{2\varsigma+4} - 12\vartheta_{2\varsigma+6}) \right],
\]

\[
f_l(\varsigma) \triangleq 2 (\vartheta_{2\varsigma-1} - \vartheta_{2\varsigma+4}) \lambda'(2\varsigma-1 - 2\varsigma+4)^T - 4 (\vartheta_{2\varsigma-1} + 2\varsigma+4 - 6\vartheta_{2\varsigma+6}) \lambda'(2\varsigma-1 + 2\varsigma+4 - 6\vartheta_{2\varsigma+6})^T,
\]

\[
g_l(\varsigma) \triangleq 2 (\vartheta_{2\varsigma+2} - \vartheta_{2\varsigma+4}) \lambda' (\vartheta_{2\varsigma+2} - 4\vartheta_{2\varsigma+4} + 6\vartheta_{2\varsigma+6}) \lambda' (\vartheta_{2\varsigma+2} - 4\vartheta_{2\varsigma+4} + 6\vartheta_{2\varsigma+6})^T,
\]

\[
\mathcal{I} \triangleq \text{diag} \{ 1, 1 \},
\]

and denote the following functions, which will be used in
Theorem 1 in the sequel,

\[
\begin{align*}
\Theta_{1ijl} &\triangleq \varrho_1 \left( \sum_{m \in \mathcal{M}} \pi_{im} P_{1im} \right) \varrho_1^T - \lambda \left[ \varrho_1 P_{ll} \varrho_1^T + \varrho_1 P_{ll} \varrho_1^T \right], \\
+ S \text{sym} \left\{ \varrho_1 P_{ll} \varrho_1^T + \varrho_2 P_2 \varrho_2^T + \lambda \varrho_1 P_{ll} \varrho_1^T \right\} - \frac{2\lambda}{t_m^M} \varrho_1 T_1 \varrho_1^T + \varrho_1 (Q_{1l} + \tau_M T_1) \varrho_1^T - \varrho_1 Q_{1l} \varrho_1^T \\
+ \frac{\gamma^2}{2} \varrho_1 2 (2Q_{2l} + Q_{3l} + Q_{4l} + T_2 + \tau_M T_3) \varrho_1^T \\
- \sum_{j=1}^2 \left[ f_l(\Psi_{2jl}) + g_l(\Psi_{2jl}) + \mathcal{U}_{1ijl} \right] + \sigma_1 \varrho_1 \Omega_1 \varrho_1^T \\
- \Gamma \left[ \Xi(Q_{2l}) \varrho_1 \Psi_{1ijl} \right] \Xi(Q_{2l}) \varrho_1 \Psi_{1ijl} \\
+ \Theta_{2ijl} \triangleq D_{il} \varrho_1^T + F_{il} K_j (\varrho_0 - \varrho_0) \varrho_1^T,
\end{align*}
\]

\[
\Psi_{1} \triangleq -3 (\vartheta_{2\varsigma+4} - 2\vartheta_{2\varsigma+6}) \Phi_0 (\vartheta_{2\varsigma+4} - 2\vartheta_{2\varsigma+6})^T.
\]
\[- \omega + 4 - \theta_1 t + \frac{T}{\varepsilon} + 3 \] 

\[S \triangleq (1 + \tau_M) \max_{l \in M} \left(\lambda_{\max} (P_l)\right) + \tau_M \max_{l \in M} \left(\lambda_{\max} (Q_{l1})\right)
+ \frac{1}{2} \tau_M^2 \max_{l \in M} \left(\lambda_{\max} (Q_{l2})\right) + \frac{1}{2} \tau_M^2 \lambda_{\max} (Z_1)
+ \frac{1}{3} \tau_M^3 \max_{l \in M} \left(\lambda_{\max} (Q_{l3})\right) + \frac{1}{6} \tau_M^4 \lambda_{\max} (Z_3) ,
\]

with

\[\mathcal{U}_{ijl} \triangleq S \left\{ \begin{array}{l}
\Phi_{ijl} \triangleq \lambda Q_{l1} + T_1 - \sum_{m \in M} \pi_{lm} Q_{m1},
\Phi_{l1} \triangleq \lambda Q_{l1} + T_1 - \sum_{m \in M} \pi_{lm} Q_{m1},
\Phi_{2l} \triangleq \lambda Q_{l2} + T_2 - \tau_M \sum_{m \in M} \pi_{lm} Q_{m2},
\Phi_{3l} \triangleq \lambda Q_{l3} + (\lambda \tau_M + 1) T_3 + \lambda T_2 - \sum_{m \in M} \pi_{lm} Q_{m3},
\Phi_{4l} \triangleq \lambda Q_{l3} + T_3 - \sum_{m \in M} \pi_{lm} Q_{m3} .
\end{array} \right.\]

\[\textbf{Theorem 1:} \text{ Given scalars } \lambda > 0, \gamma > 0, a_1 > 0, a_2 > 0, \omega > 0, t_p > 0, t_M > 0, \phi \geq 1, \sigma \geq 0 \text{ and matrix } R > 0. \text{ Then system (10)-(12) is of FTB with regard to } (a_1, a_2, t_p, R, \omega), \text{ if there exist matrices } \Omega_i, G_i, \text{ symmetric matrices } \hat{P}_i \equiv \begin{bmatrix} P_{i1} & P_{i2} \\ P_{i3} & 0 \end{bmatrix} , \text{ } \begin{bmatrix} 0 & Q_{i1} & Q_{i2} & Q_{i3} \\ Q_{i4} & T_1 & T_2 & T_3 \end{bmatrix} \text{ satisfying } Q_{i4} + T_1 > 0, T_2, T_3, \text{ such that the following conditions hold for each } l \in M, \]

\[ \begin{bmatrix}
\Theta_{1kil} + \tau_M \Psi_{kl} \Theta_{2kil} * \\
* - I
\end{bmatrix} < 0, \]

\[ \begin{bmatrix}
\Xi (Q_{l1} + \Phi_{l1}) \Psi_{kl} \Theta_{2kil} * \\
* * - I
\end{bmatrix} > 0, \]

\[ \begin{bmatrix}
\Xi (Q_{l2} + \Phi_{l2}) \\
* \Xi (Q_{l3} + Q_{l4})
\end{bmatrix} > 0,
\]

\[\exp (\lambda t_p) S \Omega_1 + \exp (\lambda t_p) \gamma^2 \omega \leq a_2 .\]
\[
- \tau(t) \int_{t^{-}\tau(t)}^{t} \dot{x}(t) Q_{3} x(t) \, dt \\
- \int_{-\tau}^{0} \int_{t^{-}\tau}^{t} \dot{x}(t) \Phi_{3} x(t) \, d\alpha d\gamma \\
- \int_{-\tau}^{0} \int_{t^{-}\tau}^{t} \dot{x}(t) \Phi_{4} x(t) \, d\alpha d\tau 
\]

where

\[
\begin{align*}
\xi(t) &\triangleq [\xi_{1}(t) \xi_{2}(t) \xi_{3}(t) \xi_{4}(t) \xi_{5}(t) \xi_{6}(t)]^{T}, \\
\xi(t) &\triangleq [x(t) \dot{x}(t) x(t \tau(t)) x(t \tau(t))]^{T}, \\
\xi(t) &\triangleq \left[ c_{1} \int_{t^{-}\tau(t)}^{t} x(t) \, d\alpha \right] \left[ c_{2} \int_{t^{-}\tau(t)}^{t} x(t) \, d\alpha \right], \\
\xi(t) &\triangleq \left[ c_{1} \int_{t^{-}\tau(t)}^{t} \dot{x}(t) \, d\alpha \right] \left[ c_{2} \int_{t^{-}\tau(t)}^{t} \dot{x}(t) \, d\alpha \right], \\
\xi(t) &\triangleq \left[ \int_{t^{-}\tau(t)}^{t} x(t) \, d\alpha \right] \left[ \int_{t^{-}\tau(t)}^{t} \dot{x}(t) \, d\alpha \right].
\end{align*}
\]

From (16), we can see that \(\Phi_{11} > 0, \Phi_{21} > 0, \Phi_{4} > 0\). Then applying the inequalities in Lemma 5.1 in [17], it leads to

\[
\begin{align*}
- \int_{t^{-}\tau(t)}^{t} x(t) \Phi_{11} x(t) \, d\alpha &\leq - (\tau_{M} - \tau(t)) \xi^{T}(t), \\
\int_{0}^{t} \dot{x}(t) \Phi_{11} x(t) \, d\alpha &\leq - (\tau_{M} - \tau(t)) \xi^{T}(t), \\
\int_{0}^{t} \dot{x}(t) \Phi_{11} x(t) \, d\alpha &\leq - (\tau_{M} - \tau(t)) \xi^{T}(t), \\
\int_{0}^{t} \dot{x}(t) \Phi_{11} x(t) \, d\alpha &\leq - (\tau_{M} - \tau(t)) \xi^{T}(t), \\
\int_{0}^{t} \dot{x}(t) \Phi_{11} x(t) \, d\alpha &\leq - (\tau_{M} - \tau(t)) \xi^{T}(t),
\end{align*}
\]

Additionally, from (10), for matrices \(Y_{1}\) and \(Y_{2}\) with any compatible dimensions the following equality holds:

\[
E \{ L \{ \exp(-\lambda t) \} \}
\]

In view of (19)-(31), it follows that

\[
E \left\{ \sum_{i=1}^{r} \sum_{j=1}^{r} \rho_{ij} h_{i} h_{j} \xi^{T}(t) \exp(-\lambda t) \left[ \Theta_{ij} + \Theta_{ij}^{T} \Theta_{ij} \right] \right\} \\
= E \left\{ \sum_{i=1}^{r} \sum_{j=1}^{r} \rho_{ij} h_{i} h_{j} \xi^{T}(t) \exp(-\lambda t) \left[ \Theta_{ij} + \Theta_{ij}^{T} \Theta_{ij} \right] \right\}
\]

Using Schur complement and Lemma 2, (13)-(14) imply that

\[
E \left\{ \sum_{i=1}^{r} \sum_{j=1}^{r} \rho_{ij} h_{i} h_{j} \xi^{T}(t) \exp(-\lambda t) \left[ \Theta_{ij} + \Theta_{ij}^{T} \Theta_{ij} \right] \right\} \\
= E \left\{ \sum_{i=1}^{r} \sum_{j=1}^{r} \rho_{ij} h_{i} h_{j} \xi^{T}(t) \exp(-\lambda t) \left[ \Theta_{ij} + \Theta_{ij}^{T} \Theta_{ij} \right] \right\}
\]

When \(\phi = 1\), as pointed out in Remark 2, the membership functions used in the controller are the same with the fuzzy plant and \(\frac{\rho_{j}}{\rho_{i}} \equiv 1\). In this case, it can be obtained from (34) and (35) that for \(i < j\), the following inequality holds:

\[
0 > \Theta_{i} + \Theta_{i}^{T} \Theta_{i} + \tau(t) \Psi_{i} + \tau(t) \Psi_{i}^{T} \Psi_{i}
\]
When $\phi > 1$, define $g_1 = \frac{\phi - \left(\frac{\phi}{\phi - 1}\right)}{\phi - 1} \geq 0$, $g_2 = \frac{\left(\frac{\phi}{\phi - 1}\right) - \frac{1}{\phi - 1}}{\phi - 1} \geq 0$.
Since $\phi \geq \frac{2}{\rho_1}$, it could be obtained from (34) and (35) that for $i < j$, the following inequality holds:

$$
0 > g_1 \left( \Theta_{1ijl} + \frac{\rho_i}{\rho_j} \Theta_{1ilj} + \Theta_{2ilj} \Theta_{2jil} \right) + \rho_i \Theta_{2jil} \Theta_{2jil} + (\tau (t) - \tau_M - \tau (t)) \Psi_{1l} + (\tau_M - \tau (t)) \Psi_{2l},
$$

that is,

$$
0 > \Theta_{1ijl} + \frac{\rho_i}{\rho_j} \Theta_{1ilj} + \Theta_{2ilj} \Theta_{2jil} + \rho_i \Theta_{2jil} \Theta_{2jil} + (\tau (t) - \tau_M - \tau (t)) \Psi_{1l} + (\tau_M - \tau (t)) \Psi_{2l},
$$

(37)

It follows from (32), (33), (36) and (37) that for $\phi \geq 1$, the inequality is established as below:

$$
E \left\{ \mathcal{L} \{ \exp (-\lambda t) V (x (t), \delta (t), t) \} \right\} \leq - \exp (-\lambda t) \left[ z^T (t) z (t) - \gamma^2 \omega^T (t) \omega (t) \right].
$$

Integrating both sides of (38) from 0 to $t$ and taking the expectation, it may be calculated that for each $l \in \mathbb{M}$

$$
E \left\{ \exp (-\lambda t) V (x (t), \delta (t), t) \right\} \leq E \left\{ \int_0^t \exp (-\lambda s) \left[ z^T (s) z (s) + \gamma^2 \omega^T (s) \omega (s) \right] ds \right\} + E \left\{ V (x (0), \delta (0), 0) \right\}.
$$

Since $\lambda > 0$ and $\exp (-\lambda s) < 0$ for $0 < s < t \leq t_p$, it follows from (39) that

$$
0 < E \left\{ V (x (t), \delta (t), t) \right\} \leq E \left\{ \exp (\lambda t) \int_0^t z^T (s) z (s) ds \right\} + \exp (\lambda t) \times E \left\{ V (x (0), \delta (0), 0) + \gamma^2 \int_0^t \omega^T (s) \omega (s) ds \right\}
$$

$$
\leq \exp (\lambda t) \left( a_1 S + \gamma^2 \bar{\omega} \right).
$$

What’s more, it is hard to observe from (18) that

$$
E \left\{ V (x (t), \delta (t), t) \right\} \geq \min_{l \in \mathbb{M}} \{ \lambda_{\min} (P_l) \} E \left\{ x^T (t) R x (t) \right\},
$$

which is combined to (41) and (17) implies that

$$
E \left\{ x^T (t) R x (t) \right\} \leq a_1 \exp (\lambda t) S + \exp (\lambda t) \gamma^2 \bar{\omega} \leq a_2.
$$

According to Definition 2, the CLFS is of FTB with regard to $(a_1, a_2, t_p, R, \bar{\omega})$, i.e. the condition (b) in Definition 3 is ensured.

Moreover, under zero initial condition, it can deduce from (40) that

$$
0 < E \left\{ - \exp (\lambda t) \int_0^t z^T (s) z (s) ds + \exp (\lambda t) \gamma^2 \int_0^t \omega^T (s) \omega (s) ds \right\}
$$

$$
< E \left\{ - \int_0^{t_p} z^T (s) z (s) ds + \exp (\lambda t_p) \gamma^2 \int_0^t \omega^T (s) \omega (s) ds \right\},
$$

which means that

$$
E \left\{ \int_0^{t_p} z^T (t) z (t) dt \right\} < \gamma^2 E \left\{ \int_0^{t_p} \omega^T (t) \omega (t) dt \right\},
$$

where $\gamma = \gamma \sqrt{\exp (\lambda t_p)}$. Here, one can see that the condition (b) in Definition 3 is also ensured. Therefore, in light of Definition 3, the CLFS $(\bar{\Sigma})$ is of FTB with regard to $(a_1, a_2, t_p, R, \bar{\omega})$ and accords with a prescribed $\mathcal{H}_\infty$ performance level $\gamma$. This completes the proof.

**Remark 5:** Theorem 5 provides a bounded real lemma for the resulting CLFS (10)-(12). To reduce the conservatism of the obtained condition, some integral inequalities introduced in Lemma 5.1 in [17], which present tighter upper bounds than those gained by extended Wirtinger inequality or Jensen inequality in [27], are employed in this paper. For the same reason, some double integral terms, e.g., $\int_0^{t_p} \int_0^t \omega (s) \Phi_{1l} \omega (s) ds dt$, $\int_0^{t_p} \int_0^t \omega (s) \Phi_{1l} \omega (s) ds dt$ are introduced in the state-augmented vector $\xi (t)$.

**Remark 6:** Like most of the literature on the analysis of Markov jump delayed systems, some mode-dependent matrices (that is, $P_l, Q_{1l}, Q_{2l}, Q_{3l}, Q_{4l}$) are employed in the proposed Lyapunov functional. In the derivation of the weak infinitesimal operator $\mathcal{L}$, one has to ensure that $\Phi_{vl} > 0$, $v = 1, 2, 3, 4$. In the existing results, such a condition (i.e., (16)) was not fully considered in presenting the main conditions (like (13) and (14) in Theorem 1). Since it is easy to see that $-\Phi_{vl} < 0$, $v = 1, 2, 3, 4$, the inequality conditions (13) and (14) can become more feasible by adding some terms including $\Phi_{vl}$, $v = 1, 2, 3, 4$, such as $-\Phi_{vl} + \Phi_{vl}$, $-3 (Q_{1l} - 2 \Phi_{vl})$, $-2 \Phi_{vl} - 2 \Phi_{vl} + 2 \Phi_{vl} + 2 \Phi_{vl}$, $-\mathcal{F}_1$, $-\mathcal{F}_2$.

On the basis of the FTB $\mathcal{H}_\infty$ performance analysis criterion conducted above, we are now in a position to address the design issue of an $\mathcal{H}_\infty$ controller by using an ETCS. The following theorem therefore puts forward the sufficient condition which ensures that the solutions to such an issue are existed. Before presenting the Theorem 2, we first denote the following functions, which will be used in Theorem 2 in the sequel,
\[-\Gamma \left[ \Xi (Q_{21}) \dot{g}_t \right. \left. + \Xi (Q_{22}) \right] \Gamma^T - \dot{\varrho}_0 \Delta \varrho_0^T - \dot{\gamma}^2 \varpi_0 \varpi_0' \Gamma_{00}, \right.

\[ \dot{\Theta}_{2ij} \triangleq D_{ii} \varpi_0 \varpi_0' \Gamma_{00}^T + F_{ii} K_j (q_3 - \varrho_3)^T, \]

\[ \dot{\Psi}_{cl} \triangleq -3 (\varrho_{a+6} - \varrho_{a+4}) \varphi_{ii} \Gamma_{11} (\varrho_{a+4} - \varrho_{a+6})^T \]

\[ - \varrho_{a+4} \varphi_{ii} \Gamma_{00}^T + 8 \varphi \varphi_0 \Gamma_1, \]

\[ S \triangleq (1 + \tau_M) \lambda_2 + \tau_M \lambda_3 + \frac{1}{2} \tau^2 \lambda_4 + \frac{1}{3} \tau^3 \lambda_8 + \frac{1}{6} \tau^3 \lambda_9, \]

\[ \dot{U}_{cl} \triangleq \text{Sym} \left\{ \varphi, \varphi_0, A_{ii}, T_{ii} \right\} + \varphi \varphi_0 \varphi_0' \Gamma_{00}^T, \]

\[ \dot{R} \triangleq \text{diag} \left( R, R \right), \dot{\varphi} \triangleq \text{diag} \left( I, I \right), \]

\[ \dot{\Phi}_{1l} \triangleq \lambda \tilde{Q}_{1l} + \tilde{T}_1 - \sum_{m \in M} \tilde{P}_{im} \tilde{Q}_{1m}, \]

\[ \dot{\Phi}_{2l} \triangleq \lambda \tau_M \tilde{Q}_{2l} + \tilde{Q}_{4l} + \tilde{T}_2 - \tau_M \sum_{m \in M} \tilde{P}_{im} \tilde{Q}_{4m}, \]

\[ \dot{\Phi}_{3l} \triangleq \lambda \tilde{S}_l + (\lambda \tau_M + 1) \tilde{T}_3 + \lambda \tilde{T}_2 - \sum_{m \in M} \tilde{P}_{im} \tilde{Q}_{4m}, \]

\[ \dot{\Phi}_{4l} \triangleq \lambda \tilde{Q}_{4l} + \tilde{T}_3 - \sum_{m \in M} \tilde{P}_{im} \tilde{Q}_{4m}. \]

**Theorem 2:** Given scalars \( \lambda > 0, \varrho > 0, \dot{\gamma} > 0, \alpha_1 > 0, \alpha_2 > 0, \varpi > 0, \tau_p > 0, \tau_M > 0, \theta_1, \theta_2, \phi > 0, \sigma_i > 0, \) matrices \( J_1 = \begin{bmatrix} T_{11} & T_{12} \\ T_{13} & T_{14} \end{bmatrix}, J_2 = \begin{bmatrix} \varrho & \varphi \\ \varphi & \varphi \end{bmatrix}, \) and \( R > 0. \) Then system (10)-(12) is FTB with regard to \((a_1, a_2, t_p, R, \varpi), \) and accords with a fixed \( H_{\infty} \) performance level \( \gamma = \sqrt{\exp (\lambda t_p)}. \) The gain matrices of the controller (8) are \( K_j = K_j \dot{V}^{-1} \) with the event-triggered parameters \( \varrho = \dot{V}^{-1} \omega, \) if there exist scalars \( \lambda_{g_2} (\varphi = 1, 2, \ldots, 9), \) matrices \( K_j, \Omega_i, \varphi, \dot{\varphi}, \) symmetric matrices \( \tilde{P}_i = \begin{bmatrix} \tilde{P}_{1i} & \tilde{P}_{2i} \\ \ast & \tilde{P}_{3i} \end{bmatrix}, \) \( \tilde{Q}_{4l}, \tilde{T}_l, \tilde{T}_3 > 0, \) such that the following LMIs hold for \( \varphi = 1, 2, \ldots, 9, \) \( \tau_M > 0, \) \( \tilde{P}_{3l} > 0, \) \( \tilde{Q}_{4l}, \tilde{T}_l, \tilde{T}_3 > 0, \) such that the following LMIs hold for \( \varphi = 1, 2, \ldots, 9, \) \( \tau_M > 0, \) \( \tilde{P}_{3l} > 0, \) \( \tilde{Q}_{4l}, \tilde{T}_l, \tilde{T}_3 > 0, \) and \( \gamma = \sqrt{\exp (\lambda t_p)}. \) The gain matrices of the controller (8) are \( K_j = K_j \dot{V}^{-1} \) with the event-triggered parameters \( \varrho = \dot{V}^{-1} \omega, \) if there exist scalars \( \lambda_{g_2} (\varphi = 1, 2, \ldots, 9), \) matrices \( K_j, \Omega_i, \varphi, \dot{\varphi}, \) symmetric matrices \( \tilde{P}_i = \begin{bmatrix} \tilde{P}_{1i} & \tilde{P}_{2i} \\ \ast & \tilde{P}_{3i} \end{bmatrix}, \) \( \tilde{Q}_{4l}, \tilde{T}_l, \tilde{T}_3 > 0, \) such that the following LMIs hold for \( \varphi = 1, 2, \ldots, 9, \) \( \tau_M > 0, \) \( \tilde{P}_{3l} > 0, \) \( \tilde{Q}_{4l}, \tilde{T}_l, \tilde{T}_3 > 0, \) and \( \gamma = \sqrt{\exp (\lambda t_p)}. \)
IV. Numerical Examples

Two examples are given in this section. In the first example, we investigate the relationship of \( \sigma_l, \phi, \tau_M, \gamma \) and obtain some conclusions. In the second example, a nonlinear mass-spring-damper mechanical system (MSDMS) is provided to explain the effectiveness and practicability of our theoretical results.

Example 1: Consider the FMsqs (1)-(2) with \( r = 2, \bar{m} = 2 \) and the following parameters:

\[
A_{11} = \begin{bmatrix} -2.4 & 1.2 \\ -0.9 & -2.25 \end{bmatrix}, \quad A_{12} = \begin{bmatrix} -2.1 & 0.45 \\ 1.95 & 0 \end{bmatrix},
\]

\[
A_{21} = \begin{bmatrix} -1.35 & 0.75 \\ -0.48 & -1.2 \end{bmatrix}, \quad A_{22} = \begin{bmatrix} -1.575 & 1.2 \\ -0.225 & -1.95 \end{bmatrix},
\]

\[
B_{11} = \begin{bmatrix} 0.24 & 0.5 \end{bmatrix}^T, \quad B_{12} = \begin{bmatrix} 0.15 & 0.3 \end{bmatrix}^T,
\]

\[
B_{21} = \begin{bmatrix} 0.63 & 1.4 \end{bmatrix}^T, \quad B_{22} = \begin{bmatrix} 0.45 & 0.13 \end{bmatrix}^T,
\]

\[
C_{11} = \begin{bmatrix} 0.5 & 0.4 \\ 0.2 & 0.3 \end{bmatrix}, \quad C_{12} = \begin{bmatrix} 0.1 & 0.6 \\ 0.8 & 0.7 \end{bmatrix},
\]

\[
C_{21} = \begin{bmatrix} 0.15 & 0.32 \\ 0.54 & 0.21 \end{bmatrix}, \quad C_{22} = \begin{bmatrix} 0.16 & 0.23 \\ 0.3 & 0.45 \end{bmatrix},
\]

\[
D_{11} = D_{12} = [0 \quad -0.1], \quad D_{21} = D_{22} = [0.1 \quad 0],
\]

\[
F_{11} = F_{12} = 0.1, \quad F_{21} = F_{22} = 0.3,
\]

\[
\tau_1 = -0.1, \quad \tau_2 = -0.8.
\]

The fuzzy basis functions are given as

\[
h_1(x_1(t)) = 1 - \frac{x_1^2(t)}{0.8165^2}, \quad h_2(x_1(t)) = \frac{x_1^2(t)}{0.8165^2},
\]

where \( x_1(t) \in [-0.8165, 0.8165] \).

Algorithm I: Maximizing \( \tau_M \)

Step I: Given some values for scalars \( \lambda, \gamma, \sigma_1, \sigma_2, \phi, \theta_1, \theta_2, \theta, \sigma_l \), matrices \( J_{\phi_l}(\varphi_l = 1, 2, \ldots, 8) \) and \( R \).

Step II: Given an accuracy coefficient \( \Delta \tau \) and a search upper bound \( \tau_\text{max} \) for \( \tau_M \). Then let \( \tau_- = 0 \).

Step III: Let \( \tau = \frac{\tau_\text{max} + \tau_-}{2} \)

and solve the LMIs in Theorem 2.

Step IV: If LMIs in Theorem 2 are feasible and \( \tau - \tau_- \leq \Delta \tau \), then \( \tau_M \text{max} = \tau \), End; else go to Step V.

Step V: If LMIs in Theorem 2 are feasible and \( \tau - \tau_- > \Delta \tau \), then let \( \tau_+ = \tau \) and go back to Step III; else go to Step VI.

Step VI: If LMIs in Theorem 2 are unfeasible and \( \tau - \tau_- > \Delta \tau \), then let \( \tau_+ = \tau \) and go back to Step III; else let \( \tau = \tau_- \) and solve the LMIs in Theorem 2.

Step VII: If LMIs in Theorem 2 are feasible, then \( \tau_M \text{max} = \tau \), End; else restart Step I with other values.

Let \( \lambda = 0.1, \theta_1 = \theta_2 = 1, \sigma_1 = 1, \sigma_2 = 1.5, \tau_p = 10, \phi = 0.64, J_{11} = J_{14} = \text{diag} \{0.1, 0.1\}, J_{12} = J_{13} = 0, J_{\varphi_1} = \text{diag} \{1, 1\} \) \( (\varphi_l = 2, 3, \ldots, 8) \) and the exogenous disturbance input \( \omega(t) = \begin{bmatrix} \sqrt{0.0032} \omega^T(t) \\ \sqrt{0.0032} \omega^T(t) \end{bmatrix} \). Then we can see that \( \int_0^\tau \omega^T(t) \omega(t) dt \leq \bar{\omega} = 0.64 \). Firstly, applying Theorem 2 with \( \gamma = 0.5 \), the relationship between \( \tau_M \), \( \sigma_l \) \( (l = 1, 2) \) and \( \phi \) is analyzed with the aid of Algorithm I. The corresponding computation results are shown in Table I and Fig. 1, respectively. As clearly shown in Table I and Fig. 1, the maximum value of \( \tau_M \) is decreasing with \( \sigma_l \) or \( \phi \) increasing.

Moreover, using the similar method, the minimum optimal \( H_\infty \) performance \( \gamma \) can be computed by Theorem 2 with \( \tau_M = 0.3 \) for different \( \sigma_l \) \( (l = 1, 2) \) and \( \phi \), that are presented in Table II and Fig. 2, respectively. From Table II and Fig. 2, it is obvious that the minimum value of \( \gamma \) is increasing with \( \sigma_l \) or \( \phi \) increasing.

Remark 8: It should be pointed out that from Table I and Table II, we can find that the parameter \( \phi \) affects the performance of the system. It indirectly shows that the consideration of asynchronous premise variables is necessary and reasonable.

Remark 9: From Table I and Table II, one can also observe that the maximum value of \( \tau_M \) and the minimum value of \( \gamma \) are obtained at \( \sigma_l = 0 \). It is worth noting that when \( \sigma_l = 0 \), as pointed out in Remark 2, the communication scheme is time-triggered, i.e., all the SD are transmitted to the controller. These facts imply that when the network bandwidth is adequate, the system can acquire better performance by using TTCS rather than ETCS. However, it is worth pointing out that in NCSs, the communication bandwidth is a scarce resource and in this case, the TTCS may be unavailable. Fortunately, the ETCS can be employed to effectively reduce the usage of bandwidth, which will be demonstrated in the later.

Further, fixing \( \tau_M = 0.3, \sigma_1 = \sigma_2 = 0.3, \phi = 0.7, \theta = 1 \), the sampling time \( h = 0.12 \) and the other parameters are
the same as the former. The corresponding trigger parameters and gain matrices of the controller (8) can be computed by Theorem 2, which are listed as below:

$$\Omega_1 = \begin{bmatrix} 11.5949 & -14.0135 \\ -14.0135 & 30.1296 \end{bmatrix}, \quad K_1 = \begin{bmatrix} 0.2022 \\ -0.4383 \end{bmatrix}^T,$$

$$\Omega_2 = \begin{bmatrix} 68.9458 & -29.6763 \\ -29.6763 & 36.4576 \end{bmatrix}, \quad K_2 = \begin{bmatrix} 0.1740 \\ -0.4112 \end{bmatrix}^T.$$  

Firstly, the state responses of the open-loop system in Fig. 3 indicate that the open-loop system is not FTB. Then, under the obtained trigger parameters and gain matrices of the controller (7), the transmit interval is plotted in Fig. 4. The state responses of the CLFS, $x^T(t)Rx(t)$ and possible mode evolution are plotted in Fig. 5, where $x(0) = \begin{bmatrix} -0.4 & 0.8 \end{bmatrix}^T$. From Fig. 4, we can compute that only about 4.8077% of all SD are transmitted to the controller within simulation duration 50s, which testifies that the ETCS can effectively reduce the usage of bandwidth. From Fig. 5, we can see that the CLFS is of FTB, which means that the developed design approach in this work is effective.

**Example 2**: Consider the following nonlinear MSDMS modified from [14], which is illustrated in Fig. 6.

$$M \ddot{\theta}(t) + D(\dot{\theta}(t)) \dot{\theta}(t) + k\theta(t) = \psi_1 u(t) + \psi_2 \omega_1(t),$$

where the physical meaning and nominal values of the parameters are given in Table III.

Moreover, in this paper, we assume that $k$ is unknown but have four different modes, i.e. 100%, 102%, 104% and 108% of its nominal values. The switching between four different modes is assumed to follow a Markov process with the TPM

II given as:

\[
\Pi = \begin{bmatrix}
-0.3 & 0.15 & 0.05 & 0.1 \\
0.1 & -0.2 & 0.05 & 0.05 \\
0.03 & 0.04 & -0.1 & 0.03 \\
0.3 & 0.1 & 0.4 & -0.8
\end{bmatrix}.
\]

Choosing the augmented state as \( x(t) = [x_1(t) \ x_2(t)]^T \), a state-space representation of the MSDMS can be yielded as follows:

\[
\dot{x}_1(t) = (-0.75x_1^2(t) - 0.5)x_1(t) + u(t) - 0.1(1 + \mu(\delta(t)))x_2(t) + \omega_1(t), \quad (57)
\]

\[
\dot{x}_2(t) = x_1(t), \quad (58)
\]

where

\[
\mu(\delta(t) = 1) = 0.0, \quad \mu(\delta(t) = 2) = 0.02,
\]

\[
\mu(\delta(t) = 3) = 0.04, \quad \mu(\delta(t) = 4) = 0.08.
\]

Choosing \( \omega(t) \) as \( \omega(t) = [\omega_1(t) \ \omega_2(t)]^T \) and by adopting the same fuzzy sets used in [14], the system (57)-(58) can be reconstructed as follows:

**Plant rule 1:** If \( x_1(t) \) is about \( \Gamma_1 \), THEN

\[
\dot{x}(t) = A_1(\delta(t))x(t) + B_1(\delta(t))u(t) + C_1(\delta(t))\omega(t),
\]

\[
z(t) = D_1(\delta(t))x(t) + F_1(\delta(t))u(t).
\]

**Plant rule 2:** If \( x_1(t) \) is about \( \Gamma_2 \), THEN

\[
\dot{x}(t) = A_2(\delta(t))x(t) + B_2(\delta(t))u(t) + C_2(\delta(t))\omega(t),
\]

\[
z(t) = D_2(\delta(t))x(t) + F_2(\delta(t))u(t),
\]

where \( \Gamma_1, \Gamma_2 \) are defined in [14] and

\[
A_1(\delta(t)) = \begin{bmatrix}
-0.5 & -0.1(1 + \mu(\delta(t))) \\
1.0 & 0.0
\end{bmatrix},
\]

\[
A_2(\delta(t)) = \begin{bmatrix}
-1.0 & -0.1(1 + \mu(\delta(t))) \\
1.0 & 0.0
\end{bmatrix},
\]

\[
B_1(\delta(t)) = B_2(\delta(t)) = \begin{bmatrix}
1.0 & 0.0
\end{bmatrix}^T,
\]

\[
C_1(\delta(t)) = C_2(\delta(t)) = \text{diag} \{1.0, 0.0\},
\]

\[
D_1(\delta(t)) = D_2(\delta(t)) = \begin{bmatrix}
1.0 & 2.0
\end{bmatrix},
\]

\[
F_{11} = 0.1, \quad F_{12} = 0.2, \quad F_{13} = -0.1,
\]

\[
F_{14} = 0.3, \quad F_{21} = 0.2, \quad F_{22} = 0.3,
\]

\[
F_{23} = -0.7, \quad F_{24} = 0.7, \quad \delta(t) = 1, 2, 3, 4.
\]

In addition, let the exogenous disturbance input be \( \omega_2(t) = \frac{\omega(t)}{1 + 2s} \). Applying Theorem 2 with the following parameters

\[
\tilde{\gamma} = 0.8, \quad \sigma_1 = 0.3(l = 1, 2, 3, 4), \quad \lambda = 0.1, \quad \phi = 1, \quad \theta_1 = \theta_2 = 1, \quad \tau_M = 0.3, \quad a_1 = 1, \quad a_2 = 3, \quad t_p = 10,
\]

\[
\bar{\omega} = 0.64, \quad \mathcal{J}_{11} = \mathcal{J}_{14} = \text{diag} \{0.1, 0.1\}, \quad \mathcal{J}_{12} = \mathcal{J}_{13} = 0, \quad \mathcal{J}_{\varphi_1} = \text{diag} \{1, 1\} \{\varphi_1 = 2, 3, \ldots, 8\},
\]

the corresponding trigger parameters and gain matrices of the controller (8) are obtained:

\[
\Omega_1 = \begin{bmatrix}
36.3029 & 21.3056 \\
21.3056 & 14.7233
\end{bmatrix}, \quad \Omega_2 = \begin{bmatrix}
36.0814 & 21.2761 \\
21.2761 & 14.7033
\end{bmatrix},
\]

\[
\Omega_3 = \begin{bmatrix}
31.8305 & 19.4141 \\
19.4141 & 13.1587
\end{bmatrix}, \quad \Omega_4 = \begin{bmatrix}
43.9538 & 25.2538 \\
25.2538 & 18.5945
\end{bmatrix},
\]

\[
K_1 = \begin{bmatrix}
-1.5243 & -0.9808
\end{bmatrix}, \quad K_2 = \begin{bmatrix}
-1.5330 & -1.0134
\end{bmatrix}.
\]

Under the obtained trigger parameters and gain matrices of the controller (7), the transmit interval is plotted in Fig. 7. The state responses of the CLFS, \( x^T(t) R x(t) \) and possible mode evolution are plotted in Fig. 8 where \( x(0) = [-0.1 \ 0.8]^T \). From Fig. 7, it can be computed that only about 6.6895% of all SD are transmitted to the controller within simulation duration 70s, which means that the communication burden is largely reduced by using the proposed ETCS. From Fig. 8, one can see that the CLFS is of FTB, which indicates the availability of the developed design approach.

**V. CONCLUSIONS**

The issue of event-triggered finite-time \( H_\infty \) control for T-S FMJSs with asynchronous premises is investigated in this paper. The ETCS is employed to reduce the communication burdens. By using the asynchronous premise reconstruct method, the asynchronous constraints on membership functions are well utilized. Moreover, by utilizing finite-time analysis theory and Lyapunov–Krasovskii approach, some sufficient conditions for finite-time boundness with a prescribed \( H_\infty \) performance analysis of the considered system have been derived and the corresponding \( H_\infty \) controller design have been carried out. Finally, both a numerical example and a nonlinear MSDMS are provided to show the utilizability and practicability of our theoretical results. It is noteworthy that the
results presented in this work can be broadly extended to more complex FMJSs, such as FMJSs with parametric uncertainties, fuzzy semi-MJSs and delayed FMJSs, which deserves further exploration.
