Designs of Borders: Security, Critique and the Machines

Journal:	<i>European Journal of International Security</i>
Manuscript ID	EJIS-0079-20.R1
Manuscript Type:	Research Article
Keywords:	Border, Security research, Technology, European Union, Critique
Abstract:	<p>Over the past 15 years, the European Commission has poured millions of Euros into Research & Development in border security. This article looks at the devices that are funded under this scheme. To this end, it applies Multiple Correspondence Analysis to a database of 41 projects funded under 7th Framework Programme. This method of data visualisation unearths the deep patterns of opposition that run across the sociotechnical universe where European borders are designed and created. We identify three rationalities of power at play: territorial surveillance aimed at detecting rare events in remote areas, policing of dense human flows by sorting out the benign from the dangerous, and finally global dataveillance of cargo on the move. Instead of trends towards either the hardening of borders or their virtualisation, we, therefore, find multiple rationalities of power simultaneously redefining the modalities of control at EU borders. A second finding shows where precisely critical actors are located in this sociotechnical universe and indicates that the structure of European R&D in border security keeps irregularised migrants off their radars. This finding calls for more caution as to the possibility to effectively put critique to work within the context of EU R&D.</p>

Introduction

Faced with the conundrum of reconciling Brexit and the Friday agreement, Theresa May suggests in February 2019 that ‘technology could play a part (...) for the particular circumstances of Northern Ireland.’¹ With those words, the Prime Minister endows technologies with the ‘myth of infallibility’ that undergirds most politicians’ beliefs when it comes to border security (Piazza, 2008).² In this article, we look into technological devices as they are imagined, designed and tested. We centre on the rationalities of power that they are locked into even before they reach their market, i.e. the professionals of security. This empirical angle brings into focus practices of Research and Development (R&D) whereby small businesses, large industrial consortia, Science and Technology departments (STS), applied research centres and others fashion distinct understandings of border security. The funding of R&D distributes material and symbolic

assets to engineers and managers of the private industries, who get a say into what border security is, and is not.

As a matter of fact, EU research policy is one of the social universes where the logics of the European field of security are currently making headway.³ In the early 2000s, civil servants from DG Enterprise set up a high-level public-private dialogue on the security industry which fashioned a depoliticized understanding of security. Security was presented as neutral technique that would provide easy answers to complicated questions.⁴ Such a definition conceals the political role that technologies play, especially as they interact with humans and take on agency of their own.⁵ This approach provided the backbone of the 7th Framework Research Programme (FP7) that funded 41 projects dedicated to border security between 2007 and 2013. This R&D programme epitomizes

‘the emergence of the civil security market as a priority in EU policymaking’.⁶ Yet, we know little of the kind of border security that emerges from its many designs.

The available literature offers an alternative set of arguments when it comes to the interplay between border security and technological devices.⁷ Some argue that the territorial line remains the key driver of the current hardening of borders around the globe.⁸ Other insists that processes or dematerialization are currently underway, which radically redistribute controls away from the borders.⁹ In the case of the FP7, both arguments have equal merit. Both logics of territorialisation and deterritorialization undergird this scheme. But, crucially, they are supported by different actors, who enter into relations through different projects and design different devices. Divergent transformations unfold at the same time. We therefore need to question the

heterogenous process at play here. Such heterogeneity begs a different set of questions than an either/or alternative. That is why we ask which actors contribute to assembling which rationality of border control through which devices. More specifically, which projects integrate the critical analysis of social scientists or members of non-governmental organisations (NGOs) as to the 'effects of the innovations and commercialization'?¹⁰ And what does this tell us about the possibility of 'critique' through 'companionship' in EU-funded security R&D?¹¹

Answering those questions requires a significant expansion of the theoretical and methodological perspectives that inform security studies.¹² That is why we resort to a method of data visualisation called Multiple Correspondence Analysis (MCA). Popularized by Pierre Bourdieu from the mid-70s on, this method is considered standard practice in social sciences, even though it is seldom used in Security Studies.¹³ MCA brings out the structures of a statistical population described by a large set of qualitative

variables.¹⁴ In our case, we designed 97 variables to describe 41 projects of border security funded under the FP7 programme. Our endgame is to better understand the types of border security that emerge from the relations between actors, devices and rationalities unfolding across those projects.

Our argument falls in 6 parts. The first section engages the connection between practices and devices in the context of border security. It highlights the heuristic purchase that a transversal perspective on European R&D in border security can yield. The second section presents our method of data visualization. MCA processes a multiplicity of relations: the actors involved in EU border security research, the laboratories where devices are designed so as to connect to security practices, and the rationalities of power that are embedded in those devices. After laying out our dataset in segment 3, we move on to analysing our findings. Section 4 visualises an emerging social structure where two cleavages are at play. Firstly, the territorial control of space is opposed to the differential control of flows. Secondly, the facilitation of non-human flows contrasts with surveillance and control of human movement. In section 5, we move on from rationalities of power to the actors who are involved in designing devices

as producers or end-users. This move enables us, in our sixth and last segment, to locate social scientists and activists in this sociotechnical universe. In the concluding remarks, we bring those results to bear on the current post-critical enthusiasm about the possibility of critique in security research programmes subsidised by the EU Commission.

Practices, devices and rationalities of border security

This section engages with recent scholarship on practices and devices of security. It delineates the theoretical quadrilateral wherein our argument is nested. The first vertex corresponds to Didier Bigo's inquiry into the three universes of border control in Europe. The second vertex coincides with Mike Bourne, Heather L. Johnson, and Debbie Lisle's investigation into one security laboratory. The third one matches Theodore Baird's rendering of border industry in Europe. The fourth and last one symbolises the post-critical appraisal of the possibility of critique in EU security R&D.

Bigo identifies three universes that shape control practices at the external border of the EU.¹⁵ The first one pertains to the universe of the military. Those actors operate within

¹⁵ Didier Bigo, 'The (in)securitization practices of the three universes of EU border control: Military/Naval - border guards/police - database analysts', *Security Dialogue* (45(3), 2014), p. 210.

a territorial rationality of power, whereby 'the metaphor of solid walls is epitomized by an electronic system of surveillance (EUROSUR) and its local translation traces an imaginary line dividing the Mediterranean Sea between North and South'.¹⁶ The second universe is populated by policemen who manage flows of people. They set up a series of filters in order to sort out licit life and things, from illicit ones. The rationality of a liquid running through a system of locks contrasts with that of the solid line, even when this line cuts through maritime space.¹⁷ Finally, Bigo delineates a third universe featuring a deterritorialized rationality of power where borders are neither solid nor liquid: they exist in a gaseous state. IT specialists set up and maintain a digital environment where the circulation of data outpaces that of the bodies and things to which they relate.¹⁸ When bodies and things cross a port of entry, they are translated into a set of data to which inductive techniques of profiling can apply with a view to thwart abnormal or undesirable events even before they happen.¹⁹

¹⁹ Bigo (2014), pp. 217-20; See also Matthias Leese, 'The new profiling: Algorithms, black boxes, and the failure of anti-discriminatory safeguards in the European Union', *Security Dialogue* (45(5), 2014), pp. 494-511.

Bigo's analysis delivers strong heuristic pay-offs insofar as it foregrounds the multiple rationalities of power wherein borders are located. It falls short, however, of investigating the 'political economy of security' whereby devices are put in production.²⁰

Bigo's focus lies with the dispositions of policemen, officers and IT specialists. Those combine to the agency of security devices in yielding distinct bordering effects. If, however, 'security devices are the non-linear result of struggles, controversies and translations between various actors, heterogeneous conceptions, and myriad interests, goals and values,'²¹ then the conceptions, interests and values of actors who design those devices matter as well as those who operate them. The focus of the investigation must therefore shift from the fields of consumption to the fields of production of those bordering devices.

Bourne, Johnson and Lisle's article helps move the argument in this direction.²² They bring one FP7 project under close ethnographic examination. HANDHOLD aims to fashion a portable, multi-sensor device, easily deployable at the border. The authors investigate the laboratory where engineers, managers and scientists imagine how the border will operate through the mutual enrolment of devices and end-users. HANDHOLD is thus designed to enable border guards to rapidly detect and stop the

²⁰ Amicelle et al. (2015), p. 300.

²¹ *Ibid.*, p. 297.

²² Bourne et al. (2015).

transnational flows of dangerous things, ranging from soft drugs to radioactive material.

The device thus fits perfectly in the liquid rationality identified by Bigo.

This laboratory study provides a first element of answer to our overall question about the relations between devices, practices and rationalities of the border. But it only focuses on one project out of the dozens that the EU Commission has funded over the past 15 years. They reach conclusions that consequently seem difficult to generalize. The liquid rationality has indeed boarded one device, but what about the others? In the authors' words, what other 'assumptions and imaginations about bordering practice' become black-boxed in devices designed in the laboratories of the 40 remaining projects?²³ Are border guards and sniffer dogs the only 'phantom end-users' who are 'powerful in shaping the actual form, design and components of the device itself'?²⁴ Are there other phantoms, in other labs, shaping other devices? To start answering these questions, one needs to move on from the in-depth but narrow view provided by laboratory studies to a broader and more structural perspective that encompasses multiple projects at the same time and pays attention to their distinctive properties.

At first glance, such a vantage point is what Baird achieves by bringing the 'relational structure' of the border security industry into focus. Baird conceptualises the industry

²³ *Ibid.*, p. 309.

²⁴ *Ibid.*, p. 320.

as a set of 'dynamic relations among diverse actors.'²⁵ His investigation proceeds on two empirical levels. His analysis of patterns of co-participation in FP7 projects shows that private firms and applied research organizations are 'the most central actors of the network,' whereas academia and government play a secondary role.²⁶ On the other hand, he highlights the rationality of the border that surfaces from 'actor-event network' and 'actor-discourse network.'²⁷ In this regard, 'private firms, state actors, and EU agencies' share a common priority on surveillance and control, rather than rights and free movement.

Baird takes us some way into the broader landscape of bordering devices that the security industry puts together. His methodology, however, falls somewhat short of a truly relational approach. Network analysis processes social contacts that actually occurred, such as co-participation in conference panels of FP7 projects. But, even if interactions may sometimes actualise structural relations, the latter remain irreducible to the former. In other words, even in the absence of direct contacts, structures bear on practices.²⁸ By focusing on co-participation at fairs and conferences, Baird loses tracks

²⁵ Theodore Baird, 'Who speaks for the European border security industry? A network analysis', *European Security* (26(1), 2017), p. 39.

²⁶ Baird (2016), pp. 43–4.

²⁷ Baird (2017)

²⁸ Pierre Bourdieu, *Sur l'Etat : cours au collège de France 1989-1992* (Paris : Seuil, Raison d'Agir, 2011), pp. 178-80.

on the properties of actors, their dispositions and trajectories, their outlook and professional training. This appears detrimental because, as Claudia Aradau, Anthony Amicelle and Julien Jeandesboz argue, security practices occur at the intersection between actors' social dispositions, the socio-technical characteristics of devices and the broader social context where both are embedded.²⁹

Thus, whilst retaining Baird's broader outlook, it is necessary to 'think about the production of technologies in relation to the use of technologies.'³⁰ This is all the more challenging that there are multiple rationalities and actors at play. This latter point brings us to the role of SHS academics and NGO activists involved in some of these projects. Although they certainly do not overlook a range of challenges, exponents of the postcritical turn argue that EU security R&D is a fertile terrain for critique. For instance, the role that SHS scholars play either as ethical advisers or as direct participants enables them to put critique to work.³¹ We would certainly agree that these actors are sometimes able to graft their outlook onto projects' explicit objectives. For this critical hijacking to happen however, the very involvement of critically-minded actors, be they academics, activists or others, represents an insufficient but necessary condition. The

²⁹ Amicelle et al. (2015), p. 302.

³⁰ Aradau et al. (2019), p. 201.

³¹ Austin, Bellanova, Kaufmann (2019); Leese, Lidén, Nikolova (2019); Sam Weiss Evans, Matthias Leese, and Dagmar Rychnovská, 'Science, technology, security: Towards critical collaboration', *Social Studies of Science* (00(0) 2020).

key question therefore deals with the participation of critical actors in R&D projects. How does the structure of participations in R&D projects shape the scope of critique? Do critical actors participate in some projects and not others? In this sense, what are the conditions of possibility of *doing* and *mediating* critique within the broader sociotechnical universe of EU border security?

Thus, to unpack the relations between practices and devices that undergird EU R&D in border security, one needs to cater to the multiple rationalities of power at play when engineers design the devices that will eventually materialise EU borders. Such a perspective is needed to embrace the wider social space where border laboratories are located. Indeed, what happens within those laboratories owes, for a great part, to the positional properties that attach to their relative position and to one another.³² To understand this positional complexity, we visualise data pertaining to 41 R&D projects in border security funded by the EU between 2007 and 2013. The next segment explains the principles that are involved in our method of data visualisation, i.e. Multiple Correspondence Analysis (MCA).

³² Pierre Bourdieu, *Science de la science et réflexivité: cours du collège de France 2000-2001*. (Paris : Seuil, Raison d'Agir, 2001), pp. 67-8.

Visualising a socio-bureaucratic texture of R&D projects

MCA belongs to Geometric Data Analysis and applies to qualitative data. This method of data visualisation enables the inductive exploration of large sets of complex data by the means of their visual representation. In other words, it synthesizes large amounts of information that the human brain is ill-equipped to process on its own. MCA identifies the variables that capture with the utmost accuracy the specificity of each individual. It then combines those important variables into meta-variables. MCA yields a specific indicator, called 'contribution' that measures how variables weigh on the construction of those meta-variables.

Meta-variables represent axes of bidimensional planes, where statistical individuals (be they 'biological' individuals, institutions or, in our case, projects) are represented by points. That is why they are also called 'dimensions' or 'axes.' The sampled population therefore takes the shape of a cloud of points in a bidimensional plane. It is worth stressing that this cloud of points is but a bidimensional approximation of the multidimensional cloud of points to which the statistical population would correspond if it were described by every variables of the matrix, as opposed to only the

metavariables yielded by the MCA. In such an abstract cloud, there would be as many dimensions as there are variables in the matrix.

In this regard, MCA proceeds quite similarly to painters or photographers when they reduce a three-dimensional reality to a two-dimensional one – except that in the case of MCA, there are often dozens of variables and therefore dimensions in the abstract cloud. To borrow a metaphor from Julien Duval, none of us would spontaneously represent a camel with a front view. In such a perspective, one would barely distinguish the camel from a horse. The front view would not translate the defining feature of the camel. That is why we often go for the side view. This perspective captures the distinctive characteristics of the animal, most importantly the two humps on its back. What MCA does is simply to identify the bidimensional view that renders best the defining properties of the population under study³³.

In this bidimensional representation, individuals that have similar characteristics with regards to the most important variables are close to one another. Conversely, dissimilar individuals are represented by points that are further away from one another. In a nutshell, similarity translates into closeness, and dissimilarity into remoteness. By extension, individuals that are located near the origin of the graph display modal

³³ Julien Duval, 'Multiple Correspondence Analysis' available at: <https://www.politika.io/en/notice/multiple-correspondence-analysis>, accessed 3 September 2020.

properties, whereas those near the extremities have rare characteristics. Both the dimensions and the distribution of individuals in the bi-dimensional plane provide powerful props for the analysis of social spaces.³⁴ Dimensions give insight into the structures of opposition that underpin the social setting under examination. Distribution provides information as to which projects share the same properties, and which differ. Thus, MCA is well designed to answer our questions about which rationality boards which devices. It caters well to the multiplicity of actors, rationalities and devices at play and offers the possibility to map their distribution accurately. Most importantly, and contrary to interaction-based mapping such as network analysis, it focuses not on direct contacts but on the properties of the population under study.

In this regard, we looked at 41 projects in border security that the European Commission has funded between 2007 and 2013. Firstly, we studied websites, promotional material, final reports and results in briefs to collect information about involved actors, devices and the amount of funding. In rare cases where those were unavailable, we resorted to short summaries of proposed action, fully aware of the gap between those descriptions and what projects actually implement. Such gaps explain why we focused on FP7 rather

³⁴ Pierre Bourdieu, *Questions de sociologie* (Paris: Les Editions de Minuit, 1984), p. 113.

than the most recent H2020. Indeed, projects funded under this subsequent scheme were still ongoing at the time of data generation.

Secondly, we defined more 56 qualitative variables, containing a set of categories that are designed to describe each project. Simply put, variables are the questions that we want to ask to the projects, and categories are the answers. The dataset evolved continuously during the extraction of information, so as to build categories and variables that are as reliable and robust as possible. As we added material, we increased and specified further variables and categories – that is we added columns to the matrix, and possible answers to each column. Furthermore, in order to ensure consistency across the coding, we systematically backtracked and inspected variables horizontally – that is we made sure that the similar empirical asperities received the same code along the lines of the matrix.

Figure 1 and 2 feature the distribution of the 41 projects in the bi-dimensional plane yielded by the MCA. At first glance, one locates four different clusters. The bottom-right quadrant contains a highly concentrated group, including the project HANDHOLD that Bourne et al. studied. This cluster stands in opposition alongside the axis 1³⁵ to the cluster located in the bottom-left dial, where one finds for instance the project AMASS.

³⁵ Axis 1 captures 14.3% of the total variance of the population.

AMASS stands for *Autonomous maritime surveillance system*. It tests a network of automated detection buoys in wide maritime areas. Although the rationale changed along the way to include the goal of rescuing people in distress, the project was, at the beginning, aimed solely at intercepting embarkations of migrants before they reach European waters.

Around the origin of the graph, one finds a third cluster whose lowest project is TASS. TASS corresponds to *Total Airport Security System*. It aims to integrate different surveillance devices into one single solution that would enable the centralized management of passenger flows in an airport. TASS is opposed alongside the axis 2³⁶ to the project CASSANDRA and to the fourth cluster whose highest point the later represents. CASSANDRA stands for *Common Assessment and Analysis of Risk in Global Supply Chains*. In order to combine efficiency and security in the logistics of containers, it increases supply chain visibility, again by integrating pre-existing devices into one single solution.

Against this charcoal-painted background, we aim to know more not only about the bordering rationalities that are embedded in those projects and in the devices that they design, but also about the logic of oppositions according to which they are located along

³⁶ Axis 2 captures 11.1% of the total variance.

the two axes of the plane. Before we interpret the axes and the shape of the cloud, we need to explain how the variables (questions) and categories (answers) of our coding matrix were designed.

For Peer Review

Figure 1. Distribution of the 41 projects³⁷

Figure 2. Zoom on the bottom-right dial

A dataset of projects on border security

This section lays out our dataset. It is designed to connect two explorations: that of the bordering devices that the European Commission fosters through the 41 FP7 projects, and that of the actors who participate in the R&D projects. Therefore, our coding matrix contains two classes of variables: one describes the type of border security that informs

³⁷ All figures have been obtained by using 'SPAD' software.

each project and the other one pertains to the actors who participates in the projects.³⁸

In this section, we focus on the first class of variables, which contains four different rubrics.

The first rubric focuses on projects' **logical frame**. It sketches how each project problematizes border security. The first variable corresponds to the general objective that projects pursue. They can *aim* to 'accelerate licit humans', 'detect illicit humans', 'non-humans' or both, 'facilitate trade', 'secure transport' infrastructures, 'detect vehicles' and, finally, 'intercept' them. Then comes the variable *means*, which advances a systemic analysis of how projects achieve those objectives. Projects may operate for instance via authentication between the microchip and biometric data, or by putting together portable sensors. The variable *policy* highlights projects' broader context in EU policies. The modality 'CUSTOMS+' aggregates initiatives connected to the e-management of trade, the World Customs Organizations and DG TAXUD. 'FONTEX+' describes policies of external border control that are linked to the agency, the external border fund and systems border surveillance such as EUROSUR, MARSUR and CISE. Finally, 'E-BORDERS+' contains policies linked to the constitution of large databases such as the Smart Border package, the Enter/Exit System, the Registered Traveller

³⁸ Monique J. Beerli, Shoshana Fine and Philippe Frowd contributed crucially to this very tedious work. We would like to thank them for their help.

Programme, the agency EU-LISA, the Visa Information System, the Schengen Information System and the Passenger Name Record. Finally, the variable *output*, classifies the results of each project which are for instance devices such as ‘prototypes’ or ‘recommendations.’

The next rubric depicts the **bordering** rationality that both projects and their devices operate. The variable *target* describes that which devices are supposed to apply to. They may sort out bodies and their data-doubles³⁹, bodies and their personal ‘belongings’, look for ‘vehicles’, ‘planes’, ‘small boats’, ‘cargo’ in general, ‘bodies’ in general or even data *tout court*. This variable overlaps with the one describing the *milieu* wherein the device is supposed to be inserted. The *type* of border refers to where technologies are to be deployed: ‘blue,’ ‘green’ and ‘air border,’ or border crossing points (‘BCP’). We indicate ‘immaterial border’ whenever control does not happen at the border, but before or after it.

We furthermore observed that each device behaves differently in relation to space. We have constructed four categories of *spatialisation* to highlight those differences, namely ‘point,’ ‘network,’ ‘zone’ and ‘global.’ This variable shows that ‘borders’ are not

³⁹ According to Linnet Taylor Linnet and Fran Meissner, ‘data-doubles’ are turning the ‘complex’ humans’ identities into a simple standardized identity and ‘not possible to reverse-engineer or change it.’ In Taylor and Meissner, ‘A crisis of opportunity: Market-making, big data, and the consolidation of migration as risk’, *Antipode* (52(1), 2019), p. 282.

necessarily physical. This variable echoes David Newmann's remarks when he calls 'the traditionalists' those 'border scholars' who understand 'borders' as 'physical lines of separation between the States and countries of the international system [...]'.⁴⁰ In this perspective, it is worth stressing that few devices work so as to straightforwardly establish lines of control. Those that come closest to this spatialization actually work as zonal technologies rather than purely linear ones. These four variables show that the geometric figure of the line is conspicuously absent from this coding, whilst this imaginary remains often associated with borders. Thus, EU R&D in border security did not lay the groundwork for the reintroduction of physical borders after the so-called 'Migration Crisis' that Georg Löfflmann and Nick Vaughan-Williams have pointed out in several EU Member States.⁴¹

The third rubric of variables is designed to explore the type of **control** that is assembled. The variable *threats* registers the discourses of securitization that are encapsulated under the heading 'context' of final reports. In this case, we build categories that aggregate different types of threats. For instance, the category 'crime' aggregates cross-border, organized and serious crimes, as well as money laundering and cargo theft. The

⁴⁰ David Newmann, 'Borders and Bordering. Towards an Interdisciplinary Dialogue,' in *European Journal of Social Theory* 9(2), 2006), p. 172.

⁴¹ Georg Löfflmann and Nick Vaughan-Williams, 'Vernacular imaginaries of European border security among citizens: From walls to information management,' in *European Journal of International Security* (3, 2018), p. 388.

category 'crime+' corresponds to discourses where crime is linked to other threats. It should be noted that our coding accentuates rare threats. For instance, we code a material under 'crime+' where crime and immigration both appear because immigration appears more often. This choice allows us to capture slight discursive differences in terms of threat construction.

The next variable corresponds to the *rationality of control*. 'Differential control of flows' applies whenever a device accelerates licit flows whilst simultaneously decelerating illicit ones. 'Territorial control of space' describes devices that aim to expand surveillance capacities over a portion of geographical domain so as to authorize or interdict access. 'Area of security' combines those two rationalities and intensifies them at a specific location, such as harbour or airports. The next rubric of variables typifies the *modality of control* and warrants further inspection into how devices relate to data. This is what the variable *datafication* provides for in distributing projects with categories such as 'digital translocal' whenever data is extracted locally to be processed elsewhere, 'database' whenever a local device connects to a large database (VIS, SIS, etc.), or 'interoperable systems' whenever two different data systems connect to one another. The control incorporated in those devices rarely if ever operates without human intervention. It enrolls, in specific ways, human operators for whom they work – or conversely.

Our last rubric deciphers these human/non-human relations. Firstly, humans are often made to see things that would otherwise remain unseen. We therefore built a variable *visualisation* with four categories: 'none,' 'scan&vids' when simple feeds are provided to human operators, 'situational picture' when visualization yields actionable maps, and finally 'data-visualisation' in general. This variable echoes the work of many scholars who show how bordering devices, and the wider sociotechnical networks to which they connect, are geared towards visualising flows, space or events.⁴² Thus, our variable participate in shifting the debate away from a previous understanding of the relations between visibility and border politics that stressed its spectacular character.⁴³

All of these devices rely on a form of automated detection of anomalies⁴⁴ – yet another variable in our coding matrix called *detection*. Once anomalies are detected, some interventions are required from decision-making operators. The variable *decision* plots the kind of support that devices provide to them. The category 'go/no-go' refers to a binary green/red light system. Some devices are more complex and draw the attention

⁴⁴ Aradau and Blanke show how 'Anomalies have become particularly desirable for security professionals in their promise to capture the 'unknown unknowns'.' Claudia Aradau, Tobias Blanke, 'Governing others: Anomaly and the algorithmic subject of security,' in *European Journal of International Security*, (Vol. 3 (1), 2017), p. 20.

of the operator to an abnormal situation by a system of early 'warnings.' Others provide Key Performance Indicators ('KPI') as a way to keep tabs on unfolding situations. Others still go even further and suggest a series of 'countermeasures' to the human operators. Last but not least, some project exhibits mild attempts at balancing control with what might regard as more human-centred considerations. We captured these attempts under the variable *ethics*. Some mention the upholding of human rights, others the protection of privacy, others still the necessary acceptability of technologies of control. Some even combine concerns about privacy and acceptability. Finally, in some cases, projects limit themselves to inflicting no physical injury to those who might become the targets of their devices.

Altogether, this first class of variables describes which power rationalities 'board' which bordering devices. That is why we speak of 'onboard rationalities' in the next section. It should be noted that those variables are set as active in the MCA. This means that the MCA computes them to calculate the dimensions that define the bidimensional plane. In what follows, we turn to the interpretation of those dimensions.

Onboard rationalities of control: territories, passengers and containers

The crux of the matter is now to interpret the two dimensions that create the plane onto which projects and their characteristics are projected in figures 1 and 2. To carry out this task, this section relies on a set of graphs where categories are located at the barycentre of the cloud of individuals that they describe, and conversely. This enables us to seamlessly go back and forth between projects and their defining properties. Furthermore, the size of the markers is proportional to the contribution of their categories to the axes. Simply put, the larger the marker, the more relevant the category. Thus, the most important properties, those that contribute in the most potent way to shaping the dimensions, are readily accessible for interpretation. For reasons of graphic legibility, categories whose contribution falls below average do not feature in the graphs. By the same token, we provide two representations for the interpretation of axis 1. Figure 3 features the categories of the first two rubrics that contribute most to the first axis. Figure 4 does the same for the last two rubrics.

Figure 3. Axis 1 - logframe and border

Figure 4. Axis 1 - Control and interface

In the bottom left dial, projects such AMASS are located in the broader policy context of FRONTEX+ and geared towards the control of irregularised migrants. They operate mostly at sea, on the blue border, as well as in remote land areas and apply a zonal type of surveillance. To do this, they tend to network sensors so as to feed a constant datastream to Command and Control Centres, where early warnings are automatically triggered, inviting (or rather demanding) that human operators take a closer look at abnormal situations – often to dispatch teams of intervention or more targeted surveillance devices. Indeed, as is made clear by the positioning of more analytical categories such as ‘expanding monitoring’ and ‘territorial space,’ the bottom left-dial of the graph corresponds to projects that work within a **rationality of territorial control of space**, bolstered by technologies of surveillance and aimed at detecting rare events in remote areas. We therefore name this pole of the graph **territorial surveillance**.

In the bottom-right dial, one finds categories and projects that are rigorously opposed to those of the bottom-left. Projects such as DOGGIES, SNIFFLES and SNIFFER assemble prototypes that replace the chemical capacities of sniffer dogs in detecting unwanted things or humans. As such they are very similar to the project HANDHOLD that Bourne et al. have taken as the focal point of their laboratory study (Bourne et al., 2015). It is one heuristic upside of our approach to show that, far from being isolated, HANDHOLD is only one member of a pack of chemically-engineered sniffer dogs that are geared

towards detecting the molecules that emanate from drugs, explosives or even, in some cases, the human body. Also, in this cluster, one finds projects such as XP-DITE, FASPASS and ABC4EU that design new border crossing points in order to make ID checks smoother, faster and more comfortable for licit passengers, whilst at the same time intercepting illicit ones.

Both the portals and the chemical sniffer dogs boast high throughput capacity in order to insert smoothly within dense flows of passengers and goods. They may apply checks randomly or systematically and are usually deployed at points of control. Those devices tend to produce data that is exploited locally but may also be checked against large databases in order to authenticate passengers against their data-doubles. According to Huub Dijstelbloem and Dennis Broeders, these data-double create three categories of 'bodies': the privileged (trusted travellers)', 'unwanted (blacklisted terrorists, criminals and increasingly those who have trespassed against immigration law); and those who are suspect and require further scrutiny.'⁴⁵ Decisions suggested to human operators are then often a simple go/no-go alternative. In a nutshell, the bottom-right dial is organized by a **rationality of differential control** that is aimed at policing flows by accelerating licit ones and decelerating illicit ones.

⁴⁵ Huub Dijstelbloem and Dennis Broeders, 'Border surveillance, mobility management and the shaping of non-publics in Europe', *European Journal of Social Theory* (Vol. 18(1), 2015), p. 28.

Thus, axis 1 polarises a cleavage between territorial control of space aimed at detecting abnormal events that occur in a context with low background noise on the one hand, and differential control operating in dense flows on the other. In the later modality, 'control is short term and of rapid rates of turnover, but also continuous and without limit' – to borrow a phrase from Deleuze.⁴⁶ Oddly enough however, the category 'differential flows' does not stand near the extreme of axis 1, but is much more central than its counterpart 'territorial rationality'. To understand this apparent contradiction, one must move on to deciphering axis 2. Figure 5 below features the categories contributing most to the formation of this axis.

⁴⁶ Gilles Deleuze, *Postscript on the Societies of Control*. *October* 59 (Winter, 1992), p. 6.

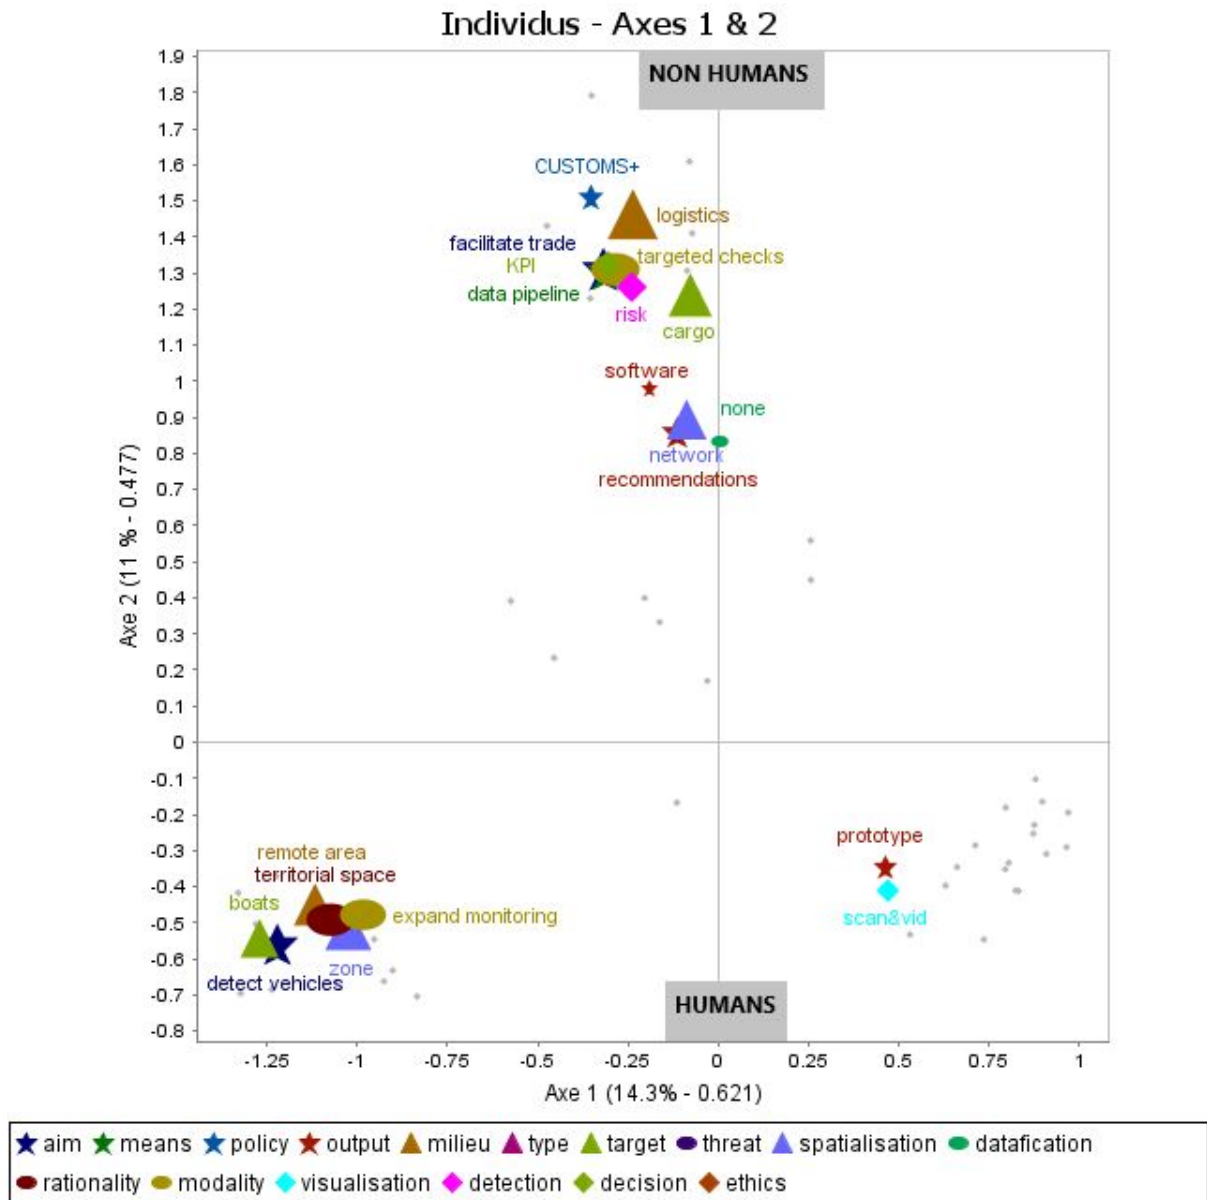

Figure 5. Axis 2

Interestingly, territorial surveillance also polarises this axis. This time however, it is opposed to a cluster located in the upper and central part of the graph. These projects tend to be located in the policy context of customs control (CUSTOMS+) and aim to facilitate trade. They develop devices that insert in the flows of containers sustaining the global supply chains upon which international trade hinges. The devices that are developed in this region of the graph are often designed to target cargo in transit by laying down a data pipeline in order to speed up pre-clearance procedures for customs administration. Such risk analysis supposedly allows the bulk of containers to move around unimpeded. Whenever checks do actually apply, some devices are designed to scan the cargo from the outside without opening the containers. CASSANDRA, CONTAIN and other projects in this cluster have to do with the globalization of things rather than with the circulation of people. The second dimension of the space therefore highlights an opposition between bordering devices aimed at humans, in the lower part, and bordering devices aimed at non-humans in the upper part.

As a result of this first step of our analysis, a triangle-shaped sociotechnical universe comes into focus, one that is reminiscent of the three rationalities of power that Bigo identified.⁴⁷ One observes a sharp differentiation between (1) the devices that

⁴⁷ Bigo (2014).

materialise the border as a **liquid** by aiming to filter legitimate travellers in dense flows (in the bottom right dial); (2) devices that materialise the border as a **solid** that expands surveillance into remote areas in order to detect rare events (in the bottom left dial); and (3) devices that materialise the border as a **gas** by focusing on non-human flows that seek to facilitate trade (in the upper part). So far, we lay exposed to the charge of having quantitatively demonstrated a trivial finding that more qualitative methods have already established. We contend, however, that such is not the case, as will become clear in the remainder of this article. We now move on from the analysis of the rationalities of border that are materially encapsulated in those devices to an examination of the actors who contribute to their design.

Consumers and producers of bordering devices

Our final aim is indeed not only to bring out the different rationalities that undergird bordering devices, but also to shed light on their designers. In this regard, our investigation takes into account the full dimensionality of 'sociomaterial configurations' whereby 'imaginaries and materialities' are *joined* together, in Lucy Suchman's words.⁴⁸

⁴⁸ Lucy Suchman, 'Configuration,' in Celia Luri and Nina Wakeford (eds), *Inventive Methods: The Happening of the Social* (Routledge, 2012), p. 48.

Our second class of variables describes ‘the designer's point of view on the user’, and vice versa.⁴⁹ It registers how both engineers and end-users contribute to designing the materiality of borders within FP7 projects. These variables are set as illustrative, which means that the MCA does not compute them to calculate the metavariabes. They are merely projected onto the bidimensional plane as it is defined by active variables. This move is instrumental in unleashing the full potential of our method. It reveals which actors stand behind which kind of bordering rationality. Figure 6 showcases the participation of the industries of defence and security. This rubric contains 4 variables: *defence industry*, *security industry*, *security consultancy* and *cyber-security*. They receive each three modalities – as is the case for all of the other variables in this class: ‘participates,’ ‘does not participate,’ ‘coordinates.’

The distribution of those illustrative variables reveals a first opposition between security firms, which specialise in commercialising technologies of detection and authentication, and the defence industry that sells heavier equipment of monitoring such as drones. The defence industry almost monopolises participation in projects assembling a territorial surveillance of remote areas, whilst the security industry is involved in sorting out flows of passengers. One observes however that defence consortia are also present in this

⁴⁹ *Ibid.* p. 56

region of the graph, which testifies to their efforts in diversifying their activities. Furthermore, a second fault line comes into focus, which opposes industrial actors in the bottom part of the graph to firms producing immaterial goods in the upper part. They both are equally involved in the bottom right dial, as much as companies selling solutions of computer security.

For Peer Review

Figure 6. Producers

Figure 7. Consumers

Our next exploration focuses not on the producers but on the consumers of those bordering devices, i.e. professionals and institutions of security. Those are often, but not always, involved in FP7 projects. Figure 7 showcases the pattern of their participation. It reveals a trenchant distinction between three actors. The military are almost exclusively involved in projects pertaining to the territorial surveillance of remote areas. The police participate in projects that focus on filtering out human flows. For these two actors, the involvement is almost exclusive. We detect only one foray of the military into the bottom right dial, and conversely. The positioning of customs administrations is more interesting in this regard. They are evenly involved in projects dealing with the policing of flows of passengers, in the bottom right dial, and projects focused on trade facilitation in the upper region of the graph.

The comparison between figures 6 and 7 brings to light a neat homology of position between producers and consumers of security devices.⁵⁰ The defence industry is located in the same region as the military. The same goes for security firms and the police, as well as customs and business intelligence. These patterns of participation qualify the widely shared belief in technological determinism that feeds both expert and scientific discourse on the dedifferentiation between the military and the police.⁵¹ One of the

⁵⁰ Bourdieu (1979), p. 257.

⁵¹ Didier Bigo, 'When two become one: Internal and external Securitizations in Europe,' in Morten Kelstrup, Michael C. Williams (eds), *International Relations Theory and the Politics of European*

analytical purchases of our approach is to cater to a reality that is more complex than a 'militarisation' of border security. In this regard, our finding shores up the following observation by Claudia Aradau and Tobias Blanke. 'Militarisation of borders [...] is not universal or even dominant, but it comes into tension with practices and discourses that focus on managing populations and 'filtering' at the border or on using data analytics to govern at a distance both spatially and temporally'.⁵²

Figures 6 and 7 not only highlight the position of police and military stakeholders but stress how each relate to distinct private partners. Instead of a single process of privatisation, one finds at least two different circuits whereby private and public actors forge competitive alliances to define what border security is and which device ought to materialize it. This stands in sharp contrast to Baird's otherwise insightful inquiry that we discussed in the above. According to him, public institutions of security are homogeneously marginal in the network that the private industry weaves. In fact, they are neither marginal nor homogeneous. Any interaction-based method such as network analysis is bound to remain oblivious to this differentiation because it does not process

Integration, Power, Security and Community (London: Routledge, 2000), pp. 171-205; Derek Lutterbeck, 'Between Police and Military: The New Security Agenda and the Rise of Gendarmeries,' in *Cooperation and Conflict* (39(1), 2004), pp. 45-68. ⁵² Aradau, Blanke (2017), p. 5.

attributional data. Only a relational method processing categorical information can render such differences. Moreover, Baird minimizes the role of border guards, police and the military. Those actors do 'not occupy central positions' in what he calls 'surveillance design communities'.⁵³ His interactional approach shows that private actors dominate the network of FP7 projects on security but fails to capture the small but meaningful distinctions among these actors, and how they relate differently to public institutions that are also different. By contrast, our approach brings another hierarchy to the fore. When they design the very devices whose multi-functionality supposedly erase the difference between the military and the police, both the military and the police stay in their corner. The core differences between these actors remain strong and meaningful. This finding echoes Bruno Martins and Christian Küsters's study dealing with EU public research funding on drones.⁵⁴ We too identify a diverse and competitive public/private partnership in the context of EU border security (police, military, customs, etc.).

Our findings also bring into focus the role that customs play in this game. This, in turn, shapes a somewhat different understanding of the economy bordering rationalities to

⁵³ Baird (2016), p. 43.

⁵⁴ Bruno Oliveira Martins and Christian Küsters, 'Hidden Security: EU Public Research Funds and the Development of European Drones,' *Journal of Common Market Studies* (Vol. 57, N° 2, 2019), pp. 278–297.

that put forth by Bigo. According to our finding, it is not the managers of large EU IT-systems of security such as EU-LISA who assemble the gaseous image of the border, but customs officials working closely with small firms of cyber-security. Quite paradoxically, although they flocked the policy-forums that set the rationale for the security scheme of the FP7,⁵⁵ those former actors remain rather discreet at the level of project implementation. It may be for the very reason that they do not apply to people that projects of trade facilitation go much further and faster in designing surveillance devices that make intensive use of inductive data-processing. In other words, the differentiation between the global dataveillance of supply chain on the one hand, policing of flows and territorial control on the other, is much more prevalent in the sociotechnical pluriverse of the European border than what Bigo found by talking solely to end-users.

With some important exceptions,⁵⁶ the role of customs professionals and projects of trade facilitation remains in the blind spot of much of the current research on border

⁵⁵ Médéric Martin-Mazé (2020).

security in Europe. Crucially, this includes critical approaches because of their overwhelming focus on issues pertaining to the free movement of people. Our last section turns to the issue of critique, R&D and border security in more details.

Critique and research: academics and activists in the machine

This section harks back to the possibility of critique in the context of EU security R&D that the first segment touched upon. To this end, it locates SHS scholars and activists in the sociotechnical universe wherein bordering devices are designed with the financial support of the European Commission. We focus on members of non-governmental organizations and SHS scholars (figure 8) because they provide a good proxy for critically-minded actors. Even though they do not hold a monopoly over critical capacity, such actors are often invited to participate in these projects for the critical voices that they may bring to the table.

At first glance, one observes that SHS scholars participate to merely 7 projects and NGOs to 5 out of 41 – which is quite low. Secondly, academics are drawn towards the pole of ‘differential control.’ Members of NGOs, for their part, are involved, somewhat surprisingly, in projects pertaining to the dataveillance of cargo. Both are kept almost completely at the bay of the pole of ‘territorial surveillance’ on the left-hand dial. This

bears some significance for the meaning of security research in general, and for the role that SHS academics play within that kind of research in particular.

For Peer Review

Figure 8. Academic and activists' critique

If, indeed, 'critique is put to work' through those projects, as Matthias Leese, Kristoffer Lidén and Blagovesta Nikolova somewhat optimistically contend,⁵⁷ the perimeter of this critique seems limited to that which regards the speed of cargo transfer, and the comfort of licit passengers at crowded airports. Critical academics in particular are enrolled in a relation of 'companionship' where, so to speak, they speed and smoothen the movement of tourists and businessmen through border control points. Increasing the speed at which the latter works, so as to improve the experience of human beings who travel legitimately seems a task of ever greater importance. But Daniele Lorenzini and Martina Tazzioli insist, rightly in our view, that other investigations are of critical significance: those carefully tracing the link between migrant death at EU borders back to the 'EU politics migration containment' as well as the 'rise of racism and xenophobia in Europe.'⁵⁸ In this regard, Bigo is on point when he asks whether 'comfort is even becoming the semantic equivalent of fundamental rights and freedom in the mind of many travellers, and speed and absence of blockade are seen as the proof of a free world in advertisements of travel agencies and in the mind of the travellers.'⁵⁹

⁵⁷ Leese et al. (2018)

⁵⁸ Daniele Lorenzini and Martina Tazzioli, 'Critique without ontology. Genealogy, collective subjects and the deadlocks of evidence,' *Radical Philosophy*, (RP 2.07, 2020), pp.27-8.

⁵⁹ Didier Bigo, 'Freedom and Speed in Enlarged Borderzones', in Vicky Squire (Ed.), *The Contested Politics of Mobility: Borderzones and Irregularity* (London: Routledge, 2011), p. 43.

The powerful but anonymous logic of European R&D in border security that this article documents, contributes to the 'political program of liberalism on a worldwide scale (which) is dedicated to freedom of movement. But it is not applied in a homogenous manner. The freedom of capital, goods, and services is a source of profitability; the freedom of human movement not necessarily so. Those who are profitable and economically solvent are to be separated from those who are not, but this must be done without checking everybody.'⁶⁰ To be clear, such structural effects do not need to be deliberate or imply calculated intent on the part of actors who would meet behind closed doors.⁶¹ Still, the implication seems clear: structural effects cut both ways when it comes to the possibility of critique and border security in Europe. We observe that both activists and SHS scholars cannot engage meaningfully with what happens to those who, precisely, are excluded from the legitimate channels of movement, because they do not participate in the projects that pertain to these actors. Those who have no choice but to travel under dangerous conditions are the target of a devices of coercion and interception that are developed under the radar of critical academics and activists simply because they are not involved in the consortia that win those tenders.

⁶⁰ Didier Bigo, 'Detention of Foreigners, States of Exception, and the Social Practices of Control of the Banopticon', in Prem Kumar Rajaramand Carl Grundy-Warr (Eds.), *Borderscapes Hidden Geographies and Politics at Territory's Edge* (Minneapolis: University of Minnesota Press, 2007), p. 30.

⁶¹ Médéric Martin-Mazé, 'Unpacking Interests in Normative Power Europe,' *Journal of Common Market Studies*, (53(6), 2015), pp. 1285-1300.

Investigating the practical logics that lead to the formation of these consortia and comparing their success rate are certainly a worthy endeavour. However, it lies beyond the scope of this article. It is worth noting that this caveat does not weaken the robustness of this particular finding: the structural conditions under which critique is made to work within the FP7 border security scheme are such that critical scholars cannot but turn a blind eye on irregularised migrants and asylum seekers. Instead, they end up holding the hands of tourists and businessmen as the happy few clear controls at border points.

Conclusion

Expansion, both functional and transnational, represents a key driver in the genesis of the field of European security.⁶² European R&D policy is but one of the latest universes where the practical logic of security professionals has made headways. Between 2007 and 2013, the European Commission funded 41 R&D projects in border security. For the most part, those activities aimed to design devices that would materialise borders in specific ways. In this article, we have asked which rationalities of power board those devices, and which actors participate in the boarding process. To answer these

⁶² Didier Bigo, *Polices en réseaux : l'expérience européenne* (Paris: Presses de Sciences Po, 1996), p. 329-31.

questions, we built a relational approach that makes use of data visualisation. Our methodological perspective brings out two fault lines that run across the sociotechnical universe of the border in Europe. The first one opposes 'territorial control of space' and 'differential control of flows,' the second one contrasts the 'surveillance of humans' to that of 'non-humans'.

Our investigation does not stop at rationalities of power, however. It also brings under examination the actors who are in the business on designing those bordering devices. Against pervasive claims about a technologically-driven dedifferentiation upon which the FP7 was itself predicated, our findings document a persistent difference between the military and the police. It should be noted that this differentiation holds true both at the level of producers and at the level of consumers. One is confronted not to one process of privatisation, but rather to two public-private circuits that lay competitive claims as to what borders ought to look like in practice and in matter. What is even more significant, however, is the position of academic researchers and activists in this sociotechnical universe of bordering devices. Those actors almost exclusively work so as to make differential control faster and, when applied to legitimate travellers, more comfortable. But they are kept away from engaging with the situation of migrants and asylum-seekers. The structures of EC-funded R&D sever this crucial relation of companionship between fragile actors and critical voices.

This article thus makes three contributions. Firstly, it moves beyond the current wave of inquiries into the agency of sociotechnical border arrangement. Most studies have so far focused mainly on how technologies play out at the border, remodelling the ways borders function, reconfiguring how border guards work, and reframing encounters with migrants. Against this backdrop, the present investigation explores what happens upstream, before the devices are deployed at the border. It sheds light on the conditions under which those devices are designed in the context of EU-funded programmes of Research & Developments. In so doing, our analysis shares the concern of Bourne et al., who carefully unpack the labour going on in border laboratories.⁶³ Yet, it foregrounds a more structural approach zooms out one specific laboratory. In order to clear any misunderstanding as to the scope of our findings, it is worth stressing a clear limitation of our investigation. Of the 41 projects that we studied at the level of their design and R&D, we did not follow them all the way through industrial production and operational deployment. In other words, the important question of which devices actually find their way to the market lies beyond the range of the present article. We would thus welcome

⁶³ Bourne et al. (2015).

further empirical research on the materialisation of these projects, particularly in relation to the contracts awarded by the European agencies of Frontex or eu-LISA.⁶⁴

Secondly, we identify which actors design which border devices into which laboratories, by visualising a space of border R&D projects with the help of Multiple Correspondence Analysis. For it stays clear of any ‘interactional fallacy,’⁶⁵ MCA performs well in rendering the structures of opposition that underpin the current ‘border struggles’ where managers, researchers and lobbyists of the security industry are increasingly involved.⁶⁶ This second, more methodological, contribution offers a deeper perspective than network analysis and wider angle than ethnographic studies of business fairs into the industry of border security.⁶⁷

Thirdly, and finally, our findings qualify the optimism of the post-critical programme in terms of the possibility of critique. To the extent that the present research has been

⁶⁴ On Frontex, see Bruno Oliveira Martins and Maria Gabrielsen Jumbert, ‘EU Border technologies and the co-production of security ‘problems’ and ‘solutions’,’ *Journal of Ethnic and Migration Studies* (2020), pp. 1-18; and Matthias Leese's work on the ‘European standardization’ of technical solutions for border security. ⁶⁷ Baird (2016; 2017)

supported by one FP7 project (SOURCE), we would certainly agree that such grants offer some leeway to SHS academics and NGO activists, critically-minded or otherwise. However, a necessary albeit insufficient condition for critique is the involvement of such actors. In this regard, our findings document the uneven participation of SHS scholars in the border security scheme of the FP7. If we agree that critique should not be reduced to 'judging the positive or negative state of the worlds we inhabit',⁶⁸ we still have to question the socio-material conditions under which we can play our role as academics in enforcing scholarly-informed critique in the context of border security. Our mapping shows how the practical logic of EU R&D in border security removes not only scholars but also activists from projects where the crudest forms of coercion are designed to target the most fragile human beings on the move. Instead, this very same practical logic channels critical voices towards situations where the only available companions happen to be privileged travellers, whose comfort and speeds are to be increased.

The extent to which this logic continues to shape H2020 lies beyond the scope of this article. However, it is worth noting with Bruno Martins and Maria Jumbert how in this case as in the case of FP7, 'the technological expertise lies with private industries, and not within scientific communities exclusively' and how 'expert knowledge-based policy-

⁶⁸ Austin, Bellanova, Kaufmann (2019), p. 15.

making has systematically increased in the EU and became mainstream in virtually all the domains of the security agenda, understood here in its widest sense.⁶⁹ Thus, if it keeps turning a blind eye on the structural dimension of social facts and security practices to replace it with a mere focus on situations, the post-critical programme runs the risk of easing the co-optation of critique by prevalent forms of power.
